

# Package ‘PriceIndices’

May 7, 2026

**Title** Calculating Bilateral and Multilateral Price Indexes

**Version** 0.3.1

**Description** Preparing a scanner data set for price dynamics calculations (data selecting, data classification, data matching, data filtering). Computing bilateral and multilateral indexes. For details on these methods see: Diewert and Fox (2020) <[doi:10.1080/07350015.2020.1816176](https://doi.org/10.1080/07350015.2020.1816176)>, Białek (2019) <[doi:10.2478/jos-2019-0014](https://doi.org/10.2478/jos-2019-0014)> or Białek (2020) <[doi:10.2478/jos-2020-0037](https://doi.org/10.2478/jos-2020-0037)>.

**Depends** R (>= 3.5.0)

**Imports** lubridate (>= 1.7.4), dplyr (>= 0.8.3), ggplot2 (>= 3.2.0), reshape, reclin2, stringr, strex

**License** GPL-3

**Encoding** UTF-8

**LazyData** true

**RoxygenNote** 7.3.3

**Suggests** testthat, knitr, rmarkdown

**VignetteBuilder** knitr

**NeedsCompilation** no

**Author** Jacek Białek [aut, cre] (ORCID: <<https://orcid.org/0000-0002-0952-5327>>)

**Maintainer** Jacek Białek <[jacek.bialek@uni.lodz.pl](mailto:jacek.bialek@uni.lodz.pl)>

**Repository** CRAN

agmean

*Calculating the bilateral AG Mean price index***Description**

This function returns a value (or vector of values) of the bilateral AG Mean price index.

**Usage**

```
agmean(data, start, end, sigma = 0.7, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>sigma</code>	The elasticity of substitution parameter (as numeric)
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral AG Mean price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

Lent J., & Dorfman, A. H. (2009). *Using a Weighted Average of Base Period Price Indexes to Approximate a Superlative Index*. Journal of Official Statistics, 25(1), 139-149.

**Examples**

```
agmean(sugar, start="2019-01", end="2020-01", sigma=0.5)
agmean(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

<code>available</code>	<i>Providing values from the indicated column that occur at least once in one of the compared periods or in a given time interval</i>
------------------------	---

---

**Description**

The function returns all values from the indicated column (defined by the `type` parameter) which occur at least once in one of the compared periods or in a given time interval.

**Usage**

```
available(data, period1, period2, type = "prodID", interval = FALSE)
```

**Arguments**

data	The user's data frame. It must contain a column <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01') and also a column indicated by the <code>type</code> parameter.
period1	The first period (as character) limited to the year and month, e.g. "2019-03".
period2	The second period (as character) limited to the year and month, e.g. "2019-04".
type	This parameter defines the column which is used in the procedure. Possible values of the <code>type</code> parameter are: <code>retID</code> , <code>prodID</code> , <code>codeIN</code> , <code>codeOUT</code> or <code>description</code> .
interval	A logical parameter indicating whether the procedure is to work for the whole time period between <code>period1</code> and <code>period2</code> (then it is <code>TRUE</code> ).

**Value**

The function returns all values from the indicated column (defined by the `type` parameter) which occur at least once in one of the compared periods or in a given time interval. Possible values of the `type` parameter are: `retID`, `prodID`, `codeIN`, `codeOUT` or `description`. If the `interval` parameter is set to `FALSE`, then the function compares only periods defined by `period1` and `period2`. Otherwise the whole time period between `period1` and `period2` is considered.

**Examples**

```
available(milk, period1="2018-12", period2="2019-12", interval=TRUE)
available(milk, period1="2018-12", period2="2019-12", type="description")
```

---

banajree

---

*Calculating the bilateral Banajree price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral Banajree price index.

**Usage**

```
banajree(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start,end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the bilateral Banajree price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function)..

Von der Lippe, P. (2007). *Index Theory and Price Statistics*. Peter Lang: Berlin, Germany.

### Examples

```
banajree(sugar, start="2018-12", end="2019-12")
banajree(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

bennet

*Calculating the Bennet price and quantity indicators*

---

### Description

This function returns the Bennet price and quantity indicators and optionally also the price and quantity contributions of individual products.

### Usage

```
bennet(
  data,
  start,
  end,
  interval = FALSE,
  matched = FALSE,
  contributions = FALSE,
  prec = 2
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical parameter indicating whether calculations are to be made for the whole time interval (TRUE) or no (FALSE).
matched	A logical parameter indicating whether the matched sample approach is to be used (if yes, the parameter has the value TRUE).
contributions	A logical parameter indicating whether contributions of individual products are to be displayed. If it is TRUE, then contributions are calculated for the the base period start and the current period end.
prec	A numeric vector indicating precision, i.e. the number of decimal places for presenting results.

**Value**

This function returns the Bennet price and quantity indicators and optionally also the price and quantity contributions of individual products.

Bialek, J. (2024). *The use of the Bennet indicators and their transitive versions for scanner data analysis*. Statistics in Transition new series, 25(3), 155-173.

**Examples**

```
bennet(milk, "2018-12", "2019-12", matched=TRUE, contributions=TRUE)
bennet(coffee, start="2018-12", end="2019-03", interval=TRUE)
```

---

 bialek

---

*Calculating the bilateral Bialek price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral Bialek price index.

**Usage**

```
bialek(data, start, end, interval = FALSE)
```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Bialek price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
bialek(sugar, start="2018-12", end="2019-12")
bialek(milk, start="2018-12", end="2020-01", interval=TRUE)
```

### Description

This function returns a value (or vector of values) of the unweighted Balk-Mehrhoff-Walsh (BMW) price index.

**Usage**

```
bmw(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	User's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the unweighted bilateral BMW price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function). This function returns values identical to those of the Dikhanov and YBMD indices (three different names for this index are used in the literature).

**Examples**

```
bmw(sugar, start="2018-12", end="2019-12")
bmw(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

carli *Calculating the unweighted Carli price index*

---

### Description

This function returns a value (or vector of values) of the unweighted bilateral Carli price index.

### Usage

```
carli(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the unweighted bilateral Carli price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

### Examples

```
carli(sugar, start="2018-12", end="2019-12")
carli(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

ccdi	<i>Calculating the multilateral GEKS price index based on the Tornqvist formula (typical notation: GEKS-T or CCDI)</i>
------	--

---

### Description

This function returns a value of the multilateral CCDI price index, i.e. the GEKS price index based on the superlative Tornqvist index formula.

### Usage

```
ccdi(data, start, end, wstart = start, window = 13)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral CCDI price index (to be more precise: the GEKS index based on the Tornqvist formula) which considers the time window defined by wstart and window parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
ccdi(milk, start="2019-01", end="2019-08", window=10)
ccdi(milk, start="2018-12", end="2019-12")
```

---

ccdi_fbew	<i>Extending the multilateral CCDI price index by using the FBEW method.</i>
-----------	--

---

**Description**

This function returns a value of the multilateral CCDI price index (GEKS based on the Tornqvist formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
ccdi_fbew(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral CCDI price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

ccdi_fbmw	<i>Extending the multilateral CCDI price index by using the FBMW method.</i>
-----------	--

---

**Description**

This function returns a value of the multilateral CCDI price index (GEKS based on the Tornqvist formula) extended by using the FBMW (Fixed Base Moving Window) method.

**Usage**

```
ccdi_fbmw(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral CCDI price index extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

ccdi_fbmw(milk, start="2019-12", end="2020-04")
```

---

ccdi_splice	<i>Extending the multilateral CCDI price index by using window splicing methods.</i>
-------------	--

---

### Description

This function returns a value (or values) of the multilateral CCDI price index (GEKS based on the Tornqvist formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

### Usage

```
ccdi_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

### Value

This function returns a value or values (depending on interval parameter) of the multilateral CCDI price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published

indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

## Examples

```
ccdi_splice(milk, start="2018-12", end="2020-02",splice="half")
```

---

chagmean

*Calculating the monthly chained AG Mean price index*

---

## Description

This function returns a value (or vector of values) of the monthly chained AG Mean price index.

## Usage

```
chagmean(data, start, end, sigma = 0.7, interval = FALSE)
```

## Arguments

- |                    |   |
|--------------------|---|
| <code>data</code>  | The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day,e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). |
| <code>start</code> | The base period (as character) limited to the year and month, e.g. "2020-03".   |
| <code>end</code>   | The research period (as character) limited to the year and month, e.g. "2020-04".   |
| <code>sigma</code> | The elasticity of substitution parameter (as numeric).  |

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start,end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the monthly chained AG Mean price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
chagmean(sugar, start="2019-01", end="2019-04", sigma=0.5)
chagmean(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chbanajree

*Calculating the monthly chained Banajree price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Banajree price index.

### Usage

```
chbanajree(data, start, end, interval = FALSE)
```

### Arguments

`data` The user's data frame with information about sold products. It must contain columns: `time` (as Date in format: year-month-day, e.g. '2020-12-01'), `prices` (as positive numeric), `quantities` (as positive numeric) and `prodID` (as numeric, factor or character).

`start` The base period (as character) limited to the year and month, e.g. "2020-03".

`end` The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start,end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

**Value**

The function returns a value (or vector of values) of the monthly chained Banajree price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

**Examples**

```
chbanajree(sugar, start="2018-12", end="2019-04")
chbanajree(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chbialek

---

*Calculating the monthly chained Bialek price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Bialek price index.

**Usage**

```
chbialek(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the monthly chained Bialek price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chbialek(sugar, start="2018-12", end="2019-04")
chbialek(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chbmw

*Calculating the monthly chained BMW price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Balk-Mehrhoff-Walsh (BMW) price index.

**Usage**

```
chbmw(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

## Value

The function returns a value (or vector of values) of the monthly chained BMW price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

chdrobisch

---

*Calculating the monthly chained Drobisch price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Drobisch price index.

**Usage**

```
chdrobisch(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the monthly chained Drobisch price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chdrobisch(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chdutot

*Calculating the monthly chained Dutot price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Dutot price index.

**Usage**

```
chdutot(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the monthly chained Dutot price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
chdutot(sugar, start="2018-12", end="2019-04")
chdutot(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chfisher

---

*Calculating the monthly chained Fisher price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Fisher price index.

**Usage**

```
chfisher(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the monthly chained Fisher price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

**Examples**

```
chfisher(sugar, start="2018-12", end="2019-04")
chfisher(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chgeary\_khamis

---

*Calculating the monthly chained Geary-Khamis price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Geary-Khamis price index.

**Usage**

```
chgeary_khamis(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the monthly chained Geary-Khamis price index depending on the interval parameter (please use `gk` function to calculate the multilateral Geary-Khamis price index). If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (see the `final_index` function).

```
chgeary_khamis(sugar, start="2018-12", end="2019-04")
chgeary_khamis(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chgeohybrid

*Calculating the the monthly chained geohybrid price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained geohybrid price index. The geohybrid index was proposed by Bialek (2020) and it uses correlation coefficients between prices and quantities.

**Usage**

```
chgeohybrid(data, start, end, base = start, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the geohybrid price index formula (as character) limited to the year and month, e.g. "2020-01"

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start, end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the monthly chained geohybrid price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
chgeohybrid(sugar, start="2019-12", end="2020-05", base="2018-12")
chgeohybrid(milk, start="2019-12", end="2020-08", base="2018-12", interval=TRUE)
```

---

chgeolaspeyres	<i>Calculating the monthly chained geo-logarithmic Laspeyres price index</i>
----------------	--

---

### Description

This function returns a value (or vector of values) of the monthly chained geo-logarithmic Laspeyres price index.

### Usage

```
chgeolaspeyres(data, start, end, interval = FALSE)
```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start,end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the monthly chained geo-logarithmic Laspeyres price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

chgeolowe

*Calculating the monthly chained geometric Lowe price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained geometric Lowe price index.

### Usage

```
chgeolowe(data, start, end, base = start, interval = FALSE)
```

### Arguments

`data` The user's data frame with information about sold products. It must contain columns: `time` (as Date in format: year-month-day, e.g. '2020-12-01'), `prices` (as positive numeric), `quantities` (as positive numeric) and `prodID` (as numeric, factor or character).

`start` The base period (as character) limited to the year and month, e.g. "2020-03".

`end` The research period (as character) limited to the year and month, e.g. "2020-04".

base	The prior period used in the geometric Lowe price index formula (as character) limited to the year and month, e.g. "2020-01"
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained geometric Lowe price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

chgeopaasche	<i>Calculating the monthly chained geo-logarithmic Paasche price index</i>
--------------	--

---

### Description

This function returns a value (or vector of values) of the monthly chained geo-logarithmic Paasche price index.

### Usage

```
chgeopaasche(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start, end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the monthly chained geo-logarithmic Paasche price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

chgeowalsh

*Calculating the monthly chained geometric Walsh price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained geometric Walsh price index

### Usage

```
chgeowalsh(data, start, end, interval = FALSE)
```

### Arguments

`data` The user's data frame with information about sold products. It must contain columns: `time` (as Date in format: year-month-day, e.g. '2020-12-01'), `prices` (as positive numeric) and `prodID` (as numeric, factor or character). A column `quantities` (as positive numeric) is also needed because this function uses unit values as monthly prices.

`start` The base period (as character) limited to the year and month, e.g. "2020-03".

`end` The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start, end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the monthly chained geometric Walsh price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

chgeoyoung

*Calculating the monthly chained geometric Young price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained geometric Young price index.

### Usage

```
chgeoyoung(data, start, end, base = start, interval = FALSE)
```

### Arguments

`data` The user's data frame with information about sold products. It must contain columns: `time` (as Date in format: year-month-day, e.g. '2020-12-01'), `prices` (as positive numeric), `quantities` (as positive numeric) and `prodID` (as numeric, factor or character).

`start` The base period (as character) limited to the year and month, e.g. "2020-03".

`end` The research period (as character) limited to the year and month, e.g. "2020-04".

base	The prior period used in the geometric Young price index formula (as character) limited to the year and month, e.g. "2020-01".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained geometric Young price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

chharmonic

*Calculating the monthly chained harmonic price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained "unnamed" harmonic price index.

### Usage

```
chharmonic(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
------	---

start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start,end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained harmonic price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chharmonic(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chhlc	<i>Calculating the monthly chained harmonic log-change (HLC) price index</i>
-------	--

---

### Description

This function returns a value (or vector of values) of the monthly chained harmonic log-change (HLC) price index

### Usage

```
chhlc(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained harmonic log-change (HLC) price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chhlc(sugar, start="2018-12", end="2019-04")
chhlc(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chybrid

---

*Calculating the the monthly chained hybrid price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained hybrid price index. The hybrid index was proposed by Bialek (2020) and it uses correlation coefficients between prices and quantities.

**Usage**

```
chybrid(data, start, end, base = start, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the hybrid price index formula (as character) limited to the year and month, e.g. "2020-01"
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained hybrid price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chIQMp	<i>Calculating the monthly chained implicit quadratic mean of order r price index</i>
--------	---

---

**Description**

This function returns a value (or vector of values) of the monthly chained implicit quadratic mean of order r price index.

**Usage**

```
chIQMp(data, start, end, r = 2, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained implicit quadratic mean of order r price index - see CPI Manual (2004), Section 17.37, formula 17.32 (page 321).

**References**

**Examples**

```
chIQMp(sugar, start="2019-01", end="2020-01")
chIQMp(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

---

chjevons

---

*Calculating the monthly chained Jevons price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Jevons price index

**Usage**

```
chjevons(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Jevons price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
chjevons(sugar, start="2018-12", end="2019-04")
chjevons(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chlaspeyres

*Calculating the monthly chained Laspeyres price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Laspeyres price index.

**Usage**

```
chlaspeyres(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Laspeyres price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chlaspeyres(sugar, start="2018-12", end="2019-04")
chlaspeyres(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chlehr

---

*Calculating the monthly chained Lehr price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Lehr price index.

**Usage**

```
chlehr(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start,end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Lehr price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chlehr(sugar, start="2018-12", end="2019-04")
chlehr(milk, start="2018-12", end="2020-01", TRUE)
```

---

 chlloyd\_moulton

*Calculating the monthly chained Lloyd-Moulton price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Lloyd-Moulton price index.

**Usage**

```
chlloyd_moulton(data, start, end, sigma = 0.7, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>sigma</code>	The elasticity of substitution parameter (as numeric).
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Lloyd-Moulton price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chlloyd_moulton(sugar, start="2018-12", end="2019-04", sigma=0.9)
chlloyd_moulton(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 chlowe

---

*Calculating the monthly chained Lowe price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Lowe price index.

**Usage**

```
chlowe(data, start, end, base = start, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the Lowe price index formula (as character) limited to the year and month, e.g. "2020-01".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Lowe price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

**Examples**

```
chlowe(sugar, start="2019-01", end="2019-04", base="2018-12")
chlowe(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chmarshall\_edgeworth *Calculating the monthly chained Marshall-Edgeworth price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Marshall-Edgeworth price index.

**Usage**

```
chmarshall_edgeworth(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Marshall-Edgeworth price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chmarshall_edgeworth(milk, start="2018-12", end="2020-01", interval=TRUE)
```

chpaasche

*Calculating the monthly chained Paasche price index***Description**

This function returns a value (or vector of values) of the monthly chained Paasche price index.

**Usage**

```
chpaasche(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Paasche price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chpaasche(milk, start="2018-12", end="2020-01", interval=TRUE)
```

chpalgrave

*Calculating the monthly chained Palgrave price index***Description**

This function returns a value (or vector of values) of the monthly chained Palgrave price index.

**Usage**

```
chpalgrave(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Palgrave price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chpalgrave(milk, start="2018-12", end="2020-01", interval=TRUE)
```

chQMp

*Calculating the monthly chained quadratic mean of order r price index***Description**

This function returns a value (or vector of values) of the monthly chained quadratic mean of order r price index.

**Usage**

```
chQMp(data, start, end, r = 2, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained quadratic mean of order r price index - see CPI Manual (2004), Section 17.40, formula 17.35 (page 321).

**References**

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

```
chQMp(sugar, start="2019-01", end="2020-01")
chQMp(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

---

chQMq	<i>Calculating the monthly chained quadratic mean of order r quantity index</i>
-------	---

---

### Description

This function returns a value (or vector of values) of the monthly chained quadratic mean of order r quantity index.

### Usage

```
chQMq(data, start, end, r = 2, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained quadratic mean of order r quantity index - see CPI Manual (2004), Section 17.35, formula 17.30 (page 321).

### References

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

### Examples

```
chQMq(sugar, start="2019-01", end="2020-01")
chQMq(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

---

chsato\_vartia                      *Calculating the monthly chained Vartia-II (Sato-Vartia) price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Vartia-II (Sato-Vartia) price index.

### Usage

```
chsato_vartia(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained Vartia-II (Sato-Vartia) price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chstuvel

*Calculating the monthly chained Stuvél price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Stuvél price index.

**Usage**

```
chstuvel(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Stuvél price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chstuvel(milk, start="2018-12", end="2020-01", interval=TRUE)
```

chtheil1

*Calculating the monthly chained Theil I price index***Description**

This function returns a value (or vector of values) of the monthly chained Theil I price index

**Usage**

```
chtheil1(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Theil I price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
chtheil1(sugar, start="2018-12", end="2019-04")
chtheil1(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

`chtheil2`*Calculating the monthly chained Theil II price index*

---

**Description**

This function returns a value (or vector of values) of the monthly chained Theil II price index

**Usage**

```
chtheil2(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the monthly chained Theil II price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

Von der Lippe, P. (2007). *Index Theory and Price Statistics*. Peter Lang, Germany, p. 232.

**Examples**

```
chtheil2(sugar, start="2018-12", end="2019-04")
chtheil2(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chtornqvist                      *Calculating the monthly chained Tornqvist price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Tornqvist price index.

### Usage

```
chtornqvist(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained Tornqvist price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

 chvartia

*Calculating the monthly chained Vartia-I price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Vartia-I price index.

### Usage

```
chvartia(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained Vartia-I price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

chwalsh\_vartia                      *Calculating the monthly chained Walsh-Vartia price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Walsh-Vartia price index

### Usage

```
chwalsh_vartia(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained Walsh-Vartia price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

`chybmd`*Calculating the monthly chained YBMD price index*

---

### Description

This function returns a value (or vector of values) of the monthly chained Young-Balk-Mehrhoff Dikhanov price index

### Usage

```
chybmd(data, start, end, interval = FALSE)
```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

### Value

The function returns a value (or vector of values) of the monthly chained Young-Balk-Mehrhoff Dikhanov (YBMD) price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function). This function returns values identical to those of the chain Dikhanov and chain BMW indices (three different names for this index are used in the literature).

chybmd(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

chyoung

*Calculating the monthly chained Young price index*

---

## Description

This function returns a value (or vector of values) of the monthly chained Young price index.

## Usage

```
chyoung(data, start, end, base = start, interval = FALSE)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the Young price index formula (as character) limited to the year and month, e.g. "2020-01".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

## Value

The function returns a value (or vector of values) of the monthly chained Young price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

coffee

*A real data set on sold coffee*

---

## Description

A collection of scanner data on the sale of coffee in one of Polish supermarkets in the period from December 2017 to October 2020

## Usage

coffee

## Format

A data frame with 6 columns and 42561 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [kg]

prodID - Unique product codes (data set contains 79 different prodIDs)

retID - Unique codes identifying outlets/retailer sale points (data set contains 20 different retIDs)

description Descriptions of sold coffee products (data set contains 3 different product descriptions)

---

compare_distances	<i>Calculating distances between price indices</i>
-------------------	--

---

## Description

The function calculates distances between price indices

## Usage

```
compare_distances(  
  data = data.frame(),  
  measure = "MAD",  
  pp = TRUE,  
  first = FALSE,  
  prec = 3  
)
```

## Arguments

data	A data frame containing values of indices which are to be compared
measure	A parameter specifying what measure should be used to compare the indexes. Possible parameter values are: "MAD" (Mean Absolute Distance) or "RMSD" (Root Mean Square Distance).
pp	Logical parameter indicating whether the results are to be presented in percentage points (then pp = TRUE).
first	A logical parameter that determines whether the first row of the data frame is to be taken into account when calculating the distance between the indices (then first = TRUE). Usually, the first row concerns the index values for the base period - all indexes are then set to one.
prec	Parameter that determines how many decimal places are to be used in the presentation of results.

## Value

The function calculates average distances between price indices and it returns a data frame with these values for each pair of price indices.

## Examples

```
#Creating a data frame with unweighted bilateral index values  
df<-price_indices(milk,  
  formula=c("jevons","dutot","carli"),  
  start="2018-12", end="2019-12",interval=TRUE)  
#Calculating average distances between indices (in p.p)  
compare_distances(df)
```

---

compare\_indices\_df     *A function for graphical comparison of price indices*

---

### Description

This function returns a figure with plots of selected price indices.

### Usage

```
compare_indices_df(
  data,
  names = colnames(data)[2:length(colnames(data))],
  date_breaks = "1 month"
)
```

### Arguments

data	The user's data frame with price index values. It must contain columns: time (as character in format: year-month, e.g. '2020-12') and columns with index values.
names	A vector of strings indicating names of indices which are to be used in the figure's legend.
date_breaks	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".

### Value

This function returns a figure with plots of previously calculated indices (together with dates on X-axis and a corresponding legend). Indices must be provided as a data frame, where the first column must include dates limited to the year and month (e.g.: "2020-04").

### Examples

```
df<-price_indices(milk, start = "2018-12", end = "2019-12",
  formula=c("laspeyres", "fisher"), interval = TRUE)
compare_indices_df(df)
```

---

compare\_indices\_jk     *A general function to compare indices by using the jackknife method*

---

### Description

This function presents a comparison of selected indices obtained by using the jackknife method.

**Usage**

```
compare_indices_jk(
  data,
  start,
  end,
  by = "prodID",
  formula = c(),
  window = c(),
  splice = c(),
  base = c(),
  sigma = c(),
  r = c(),
  names = c(),
  title_iterations = c(),
  title_pseudovalues = c()
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also essential even if the selected index is an unweighted formula (unit values are calculated).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
by	A character string which indicates a column name for creating product sub-groups (in the classical jackknife method by should indicate prodID). In each, successive repetition, the indicated price indexes are counted on the set of products reduced by the subset determined by the successive element of the column indicated by the by parameter.
formula	A vector of character strings indicating price index formulas that are to be calculated. To see available options please use the link: <a href="#">PriceIndices</a> .
window	A vector of integers. Each element of the vector defines the length of the time window of the corresponding multilateral index.
splice	A vector of character strings. Each element of the vector indicates the splicing method is to be used for the corresponding multilateral index. Available values of vector elements are: "movement", "window","half","mean" and their additional variants: "window_published", "half_published" and "mean_published".
base	The vector of prior periods used in the Young- or Lowe-type price indices or hybrid/geohybrid index. Each element of the vector (as character) must be limited to the year and month, e.g. "2020-01".
sigma	The vector of elasticity of substitution parameters used in the Lloyed-Moulton, AG Mean or GEKS-LM indices (as numeric).
r	The vector of non-zero parameters used in the quadratic mean of order r quantity / price index or in the GEKS-QM index (as numeric).

names	A vector of strings indicating names of indices which are to be used in the resulting data frame.
title_iterations	A character string indicating a title of the created box-plot for iteration index values.
title_pseudovalues	A character string indicating a title of the created box-plot for obtained (jackknife) index pseudovalues.

## Value

This function presents a comparison of selected indices obtained by using the jackknife method. In particular, it returns a list with four elements: `iterations`, which is a data frame with basic characteristics of the calculated iteration index values (means, standard deviations, coefficients of variation and results for all sample), `pseudovalues`, which is a data frame with basic characteristics of the calculated index pseudovalues obtained in the jackknife procedure (i.e. the jackknife estimators and their standard deviations and coefficients of variation), `figure_iterations` which presents a box-plot for the calculated iteration index values, and `figure_pseudovalues` which presents a box-plot for the calculated index pseudovalues obtained in the jackknife procedure.

## Examples

```

milk.<-dplyr::filter(milk, milk$prodID %in%
sample(unique(milk$prodID),4))
#creating a list with jackknife results
comparison<-compare_indices_jk(milk.,
formula=c("jevons","fisher"),
start="2018-12",
end="2019-12",
names=c("Jevons","Fisher"),
title_iterations="Box-plots for iteration values (milk products)",
title_pseudovalues="Box-plots for pseudovalues (milk products)")
#displaying results
comparison$iterations
comparison$pseudovalues
comparison$figure_iterations
comparison$figure_pseudovalues

```

---

compare\_indices\_list *A general function for graphical comparison of price indices*

---

### Description

This function returns a figure with plots of previously calculated price indices.

### Usage

```
compare_indices_list(data = list(), names = c(), date_breaks = "1 month")
```

### Arguments

data	A list of data frames with previously calculated price indices. Each data frame must consist of two columns, i.e. the first column must include dates limited to the year and month (e.g.: "2020-04") and the second column must indicate price index values for corresponding dates. The above-mentioned single data frame may be created manually in the previous step or it may be a result of functions: <code>price_index</code> or <code>final_index</code> . All considered data frames must have an identical number of rows.
names	A vector of character strings describing names of presented indices.
date_breaks	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".

### Value

This function returns a figure with plots of previously calculated price indices. It allows for graphical comparison of price index values which were previously calculated and now are provided as a list of data frames (see `data` parameter).

### Examples

```
## Calculating two indices by using two different package functions:
index1<-final_index(data=milk, start="2018-12",
end="2019-12",formula="walsh",interval=TRUE)
index2<-price_indices(milk,start="2018-12", end="2019-12",
formula="geks",window=13,interval=TRUE)
## Graphical comparison of these two indices
compare_indices_list(data=list(index1,index2),
names=c("Walsh index", "GEKS index"))
```

---

compare_to_target	<i>Calculating distances between considered price indices and the target price index</i>
-------------------	--

---

### Description

The function calculates distances between considered price indices and the target price index

### Usage

```
compare_to_target(
  data = data.frame(),
  target,
  measure = "MAD",
  pp = TRUE,
  first = FALSE,
  prec = 3
)
```

### Arguments

data	A data frame containing values of indices which are to be compared to the target price index
target	A data frame or a vector containing values of the target price index
measure	A parameter specifying what measure should be used to compare indices. Possible parameter values are: "MAD" (Mean Absolute Distance) or "RMSD" (Root Mean Square Distance).
pp	Logical parameter indicating whether the results are to be presented in percentage points (then pp = TRUE).
first	A logical parameter that determines whether the first row of the data frame and the first row of the 'target' data frame (or its first element if it is a vector) are to be taken into account when calculating the distance between the indices (then first = TRUE). Usually, the first row concerns the index values for the base period - all indexes are then set to one.
prec	Parameter that determines how many decimal places are to be used in the presentation of results.

### Value

The function calculates average distances between considered price indices and the target price index and it returns a data frame with: average distances on the basis of all values of compared indices ('distance' column), average semi-distances on the basis of values of compared indices which overestimate the target index values ('distance\_upper' column) and average semi-distances on the basis of values of compared indices which underestimate the target index values ('distance\_lower' column).

## Examples

```
#Creating a data frame with example bilateral indices
df<-price_indices(milk,
formula=c("jevons","laspeyres","paasche","walsh"),
start="2018-12",end="2019-12",interval=TRUE)
#Calculating the target Fisher price index
target_index<-fisher(milk,start="2018-12",end="2019-12",interval=TRUE)
#Calculating average distances between considered indices and the Fisher index (in p.p)
compare_to_target(df,target=target_index)
```

---

cswd

---

*Calculating the unweighted CSWD price index*

---

## Description

This function returns a value (or vector of values) of the unweighted Carruthers-Sellwood-Ward-Dalen (CSWD) price index.

## Usage

```
cswd(data, start, end, interval = FALSE)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start,end> are considered and start defines the base period (interval is set to TRUE).

## Value

The function returns a value (or vector of values) of the unweighted bilateral CSWD price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
cswd(sugar, start="2018-12", end="2019-12")
cswd(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

dataAGGR	<i>A small artificial scanner data set for a demonstration of data aggregation</i>
----------	--

---

## Description

A collection of artificial scanner data on milk products sold in three different months

## Usage

```
dataAGGR
```

## Format

A data frame with 6 columns and 9 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day: 4 different dates)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [I]

prodID - Retailer product codes (3 prodIDs)

retID - Unique codes identifying outlets/retailer sale points (4 retIDs)

description Descriptions of sold products (two subgroups: goat milk, powdered milk)

---

dataCOICOP

*A real scanner data set for the product classification*

---

**Description**

A collection of real scanner data on the sale of milk products sold in a period: Dec, 2020 - Feb, 2022.

**Usage**

dataCOICOP

**Format**

A data frame with 10 columns and 139600 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products

description - Descriptions of sold products (original: in Polish)

codeIN - Retailer product codes

retID - Unique codes identifying outlets/retailer sale points

grammage - Product grammages

unit - Sales units, e.g.: kg, ml, etc.

category - Product categories (in English) corresponding to COICOP 6 levels

coicop6 - Identifiers of local COICOP 6 groups (6 groups)

---

dataMARS

*An artificial scanner data set for testing the MARS method*

---

**Description**

An artificial scanner data set of shirt sales.

**Usage**

dataMARS

**Format**

A data frame with 9 columns and 44 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [liters]

prodID - Unique product identifiers (data set contains 28 different prodIDs)

description - Descriptions (labels) of sold shirts (data set contains 12 different descriptions)

brand - Brand of sold shirts (data set contains 2 different brands: X and Y)

gender - Gender of the person for whom the shirt is dedicated (M or F)

size - Size of shirts (M, L, and XL)

fabric - Fabric of shirts (cotton, polyester, blend)

---

dataMATCH

*An artificial scanner data set for product matching*

---

**Description**

A collection of scanner data on the sale of sample artificial products.

**Usage**

dataMATCH

**Format**

A data frame with 7 columns and 30 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [liters]

codeIN - Unique internal (retailer) product codes (data set contains 5 different codeINs)

codeOUT - Unique external product codes (data set contains 5 different codeOUTs)

retID - Unique codes identifying outlets/retailer sale points (data set contains 2 different retIDs)

description Descriptions of sold products (data set contains 3 different product descriptions)

---

dataRSM

*A real data set on sold rice, sugar and milk products*

---

### **Description**

A collection of scanner data on the sale of rice, sugar and milk products in one of Polish supermarkets in the period from December 2024 to January 2026

### **Usage**

dataRSM

### **Format**

A data frame with 9 columns and 8090 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [items]

retID - Unique codes identifying outlets/retailer sale points (data set contains 4 different retIDs)

description - Descriptions (labels) of sold products (data set contains 152 different descriptions)

retailer\_code - Retailer codes for product definition (134 retailer codes)

EAN\_code - EAN codes (bar codes) for product definition (138 EAN codes)

category - Product categories at the 6-digit COICOP level (4 categories)

subcategory - Product subcategories from 7-digit COICOP level (11 subcategories)

---

dataU

*An artificial, small scanner data set*

---

### **Description**

A collection of artificial scanner data on 6 products sold in Dec, 2018. Product descriptions contain the information about their grammage and unit.

### **Usage**

dataU

**Format**

A data frame with 5 columns and 6 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [item]

prodID - Unique product codes

description Descriptions of sold products (data set contains 6 different product descriptions)

---

data_aggregating	<i>Aggregating the user's data frame</i>
------------------	--

---

**Description**

The function aggregates the user's data frame over time and optionally over outlets.

**Usage**

```
data_aggregating(data, join_outlets = TRUE, description = FALSE, class = FALSE)
```

**Arguments**

data	The user's data frame.
join_outlets	A logical value indicating whether the data aggregation over outlets should be also done.
description	A logical value indicating whether the aggregated (returned) data frame should contain product descriptions. Please note that product codes and their descriptions are not necessarily in a 1:1 relationship. When description=TRUE, the function returns the first description encountered within a given product code (prodID).
class	A logical value indicating whether the aggregated (returned) data frame should contain product class. When class=TRUE, the function returns the first class value encountered within a given product code (prodID).

**Value**

The function aggregates the user's data frame over time and/or over outlets. Consequently, we obtain monthly data, where the unit value is calculated instead of a price for each prodID observed in each month (the time column gets the Date format: "Year-Month-01"). If the parameter join\_outlets is TRUE, then the function also performs aggregation over outlets (retIDs) and the retID column is removed from the data frame. The main advantage of using this function is the ability to reduce the size of the data frame and the time needed to calculate the price index. Please note, that unnecessary columns are removed (e.g. description).

**Examples**

```
#Example 1
data_aggregating(dataAGGR,join_outlets = FALSE)
data_aggregating(dataAGGR,join_outlets = TRUE)
#Example 2 (data frame reduction)
nrow(milk)
nrow(data_aggregating(milk))
```

---

data_check	<i>Checking the user's data frame</i>
------------	---------------------------------------

---

**Description**

The function checks if the argument `data` points to a data frame which is suitable for further price index calculation. In particular, the function checks whether the indicated data frame contains the required columns and whether they are of the appropriate type (if not, the function returns `FALSE` and an appropriate comment).

**Usage**

```
data_check(data)
```

**Arguments**

`data` Any R object but ultimately it is a data frame.

**Value**

The function returns `TRUE` if the data frame indicated by the `data` parameter is suitable for the calculation of price indices and returns `FALSE` otherwise.

**Examples**

```
data_check(milk)
data_check(iris)
```

---

data_DOWN_UP_SIZED	<i>An artificial data set on sold coffee</i>
--------------------	--

---

**Description**

A collection of scanner data on the sale of coffee in the period from January 2024 to February 2024

**Usage**

```
data_DOWN_UP_SIZED
```

**Format**

A data frame with 6 columns and 51 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)  
 prices - Prices of sold products [PLN]  
 quantities - Quantities of sold products [liters]  
 codeIN - Unique internal product codes (retailer product codes)  
 codeOUT - Unique external product codes (e.g. GTIN, EAN, SKU)  
 description - Descriptions of sold coffee products

---

data_filtering	<i>Filtering a data set for further price index calculations</i>
----------------	--

---

**Description**

This function returns a filtered data set, i.e. a reduced user's data frame with the same columns and rows limited by a criterion defined by filters.

**Usage**

```
data_filtering(  
  data,  
  start,  
  end,  
  filters = c(),  
  plimits = c(),  
  pquantiles = c(),  
  dplimits = c(),  
  lambda = 1.25,  
  interval = FALSE,  
  outlets = FALSE  
)
```

**Arguments**

data	The user's data frame with information about products to be filtered. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and quantities (as positive numeric).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
filters	A vector of filter names (options are: extremeprices, dumpprices and/or lowsales).
plimits	A two-dimensional vector of thresholds for minimum and maximum price change (it works if one of the chosen filters is extremeprices filter).

pquantiles	A two-dimensional vector of quantile levels for minimum and maximum price change (it works if one of the chosen filters is extremeprices filter).
dplimits	A two-dimensional vector of thresholds for maximum price drop and maximum drop in sales value (it works if one of the chosen filters is dumpprices filter).
lambda	The lambda parameter for lowsales filter (see References below).
interval	A logical value indicating whether the filtering process concerns only two periods defined by start and end parameters (then the interval is set to FALSE) or whether that function is to filter products sold during the whole time interval <start, end>, i.e. any subsequent months are compared.
outlets	A logical parameter indicating whether filtering should be done for each outlet (retID) separately. If it is set to FALSE, then there is no need to consider the retID column.

### Value

This function returns a filtered data set (a reduced user's data frame). If the set of filters is empty, then the function returns the original data frame (defined by the data parameter) limited to considered months. On the other hand, if all filters are chosen, i.e. filters=c(extremeprices, dumpprices, lowsales), then these filters work independently and a summary result is returned. Please note that both variants of extremeprices filter can be chosen at the same time, i.e. plimits and pquantiles, and they work also independently.

### References

Van Loon, K., Roels, D. (2018) *Integrating big data in Belgian CPI*. Meeting of the Group of Experts on Consumer Price Indices, Geneva.

### Examples

```
data_filtering(milk, start="2018-12", end="2019-03",
filters=c("extremeprices"), pquantiles=c(0.01, 0.99), interval=TRUE)
data_filtering(milk, start="2018-12", end="2019-03",
filters=c("extremeprices", "lowsales"), plimits=c(0.25, 2))
```

---

data\_imputing

*Imputing missing and (optionally) zero prices.*

---

### Description

This function imputes missing prices and (optionally) zero prices by using one of the following methods: carry forward/backward, overall mean, class mean (targeted mean).

**Usage**

```
data_imputing(
  data,
  start,
  end,
  method = "carry forward",
  class = c(),
  formula = "jevons",
  zero_prices = TRUE,
  outlets = FALSE
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as numeric), quantities (as numeric - for future calculations) and prodID (as numeric, factor or character). A column retID (as factor, character or numeric) is also needed if the User wants to impute prices over outlets.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
method	A character string indicating the imputation method. Available options are: carry forward, overall mean, class mean. For the class mean method, the class parameter must be specified.
class	A character string indicating the column which describes product classes (homogeneous subgroups).
formula	A character string indicating the index formula which will be used for the overall mean or class mean method. Available options are: dutot, carli, jevons, fisher, tornqvist, walsh.
zero_prices	A logical parameter indicating whether zero prices are to be imputed too (then it is set to TRUE).
outlets	A logical parameter indicating whether imputations are to be done for each outlet separately (then it is set to TRUE).

**Value**

This function imputes missing prices (unit values) and (optionally) zero prices by using one of the following methods: carry forward/backward, overall mean, class mean (targeted mean). The imputation can be done for each outlet separately or for aggregated data (see the outlets parameter). For the carry forward/backward method: if a missing product has a previous price then that previous price is carried forward until the next real observation. If there is no previous price then the next real observation is found and carried backward. For the overall mean method: the procedure is similar, except that the imputed price is based on the previously recorded price multiplied (or divided - in the case of the next recorded price) by the price index determined for the quoted and imputed period. The user can select the index formula via the formula parameter. For the class mean method (also known as targeted mean method): the procedure is analogous to the overall mean method, but

the price index is determined for the product class specified by the `class` parameter. The quantities for imputed prices are set to zero. The function returns a data frame (monthly aggregated) which is ready for price index calculations.

### Examples

```
# Creating a small data set with zero prices:
time.<-c("2018-12-01","2019-01-01")
time<-as.Date(c(time., time., time.))
p1<-c(0,23,10)
p2<-c(40,0,20)
q1<-c(15,25,30)
q2<-c(44,79,30)
quantities<-c(q1,q2)
prices<-c(p1,p2)
prodID<-c(1,1,2,2,3,3)
my_data<-data.frame(time, prices, quantities, prodID)
# Price imputing:
data_imputing(my_data, start="2018-12", end="2019-01",
zero_prices=TRUE, outlets=FALSE)
data_imputing(my_data, start="2018-12", end="2019-01",
zero_prices=TRUE, outlets=FALSE, method="overall mean", formula="dutot")

# Preparing a data set with zero and missing prices:
dataMATCH$prodID<-dataMATCH$codeIN
data<-dplyr::select(dataMATCH, time, prices, quantities, prodID, retID)
set1<-data[1:5,]
set1$prices<-0
set2<-data[6:30,]
df<-rbind(set1, set2)
# Price imputing:
data_imputing(df, start="2018-12", end="2019-02",
zero_prices=TRUE, outlets=TRUE)
data_imputing(df, start="2018-12", end="2019-02",
method="overall mean", zero_prices=TRUE, formula="fisher")
```

---

data\_matching

*Matching products*

---

### Description

This function returns a data set defined in the first parameter (`data`) with an additional column (`prodID`). Two products are treated as being matched if they have the same `prodID` value.

### Usage

```
data_matching(
  data,
  start,
  end,
```

```

interval = FALSE,
variables = c(),
codeIN = TRUE,
codeOUT = TRUE,
description = TRUE,
onlydescription = FALSE,
precision = 0.95
)

```

### Arguments

data	The user's data frame with information about products to be matched. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01') and at least one of the following columns: codeIN (as numeric, factor or character), codeOUT (as numeric, factor or character) and description (as character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the matching process concerns only two periods defined by start and end parameters (then the interval is set to FALSE) or whether that function is to match products sold during the whole time interval <start, end>.
variables	The optional parameter describing the vector of additional column names. Values of these additional columns must be identical for matched products.
codeIN	A logical value, e.g. if there are retailer (internal) product codes (as numeric or character) written in codeIN column and there is a need to use that column while data matching, then that parameter should be set to TRUE. Otherwise it is set to FALSE.
codeOUT	A logical value, e.g. if there are external product codes, such as GTIN or SKU (as numeric or character) written in codeOUT column and there is a need to use that column while data preparing then, that parameter should be set to TRUE. Otherwise it is set to FALSE.
description	A logical value, e.g. if there are product labels (as character) written in description column and there is a need to use that column while data preparing, then that parameter should be set to TRUE. Otherwise it is set to FALSE.
onlydescription	A logical value indicating whether products with identical labels (described in the description) are to be matched.
precision	A threshold value for the Jaro-Winkler similarity measure when comparing labels (its value must belong to the interval [0,1]). Two labels are treated as similar enough if their Jaro-Winkler similarity exceeds the precision value.

### Value

This function returns a data set defined in the first parameter (data) with an additional column (prodID). Two products are treated as being matched if they have the same prodID value. The procedure of generating the above-mentioned additional column depends on the set of chosen columns

for matching. In most extreme case, when the `onlydescription` parameter value is `TRUE`, two products are also matched if they have identical descriptions. Other cases are as follows: Case 1: Parameters `codeIN`, `codeOUT` and `description` are set to `TRUE`. Products with two identical codes or one of the codes identical and an identical description are automatically matched. Products are also matched if they have identical one of codes and the Jaro-Winkler similarity of their descriptions is bigger than the precision value. Case 2: Only one of the parameters: `codeIN` or `codeOUT` are set to `TRUE` and also the `description` parameter is set to `TRUE`. Products with an identical chosen code and an identical description are automatically matched. In the second stage, products are also matched if they have an identical chosen code and the Jaro-Winkler similarity of their descriptions is bigger than the precision value. Case 3: Parameters `codeIN` and `codeOUT` are set to `TRUE` and the parameter `description` is set to `FALSE`. In this case, products are matched if they have both codes identical. Case 4: Only the parameter `description` is set to `TRUE`. This case requires the `onlydescription` parameter to be `TRUE` and then the matching process is based only on product labels (two products are matched if they have identical descriptions). Case 5: Only one of the parameters: `codeIN` or `codeOUT` are set to `TRUE` and the `description` parameter is set to `FALSE`. In this case, the only reasonable option is to return the `prodID` column which is identical with the chosen code column. Please note that if the set of column names defined in the `variables` parameter is not empty, then the values of these additional columns must be identical while product matching.

### Examples

```
data_matching(dataMATCH, start="2018-12",end="2019-02",onlydescription=TRUE,interval=TRUE)
data_matching(dataMATCH, start="2018-12",end="2019-02",precision=0.98, interval=TRUE)
```

---

data_norm	<i>Normalization of grammage units and recalculation of prices and quantities with respect to these units</i>
-----------	---

---

### Description

The function normalizes grammage units of products and recalculates product prices and quantities with respect to these normalized grammage units.

### Usage

```
data_norm(
  data = data.frame(),
  rules = list(c("ml", "l", 1000), c("g", "kg", 1000)),
  all = TRUE
)
```

### Arguments

data	The user's data frame. The data frame must contain the following columns: prices (as positive numeric), quantities (as positive numeric), grammage (as numeric or character) and unit (as character).
------	---

rules	User rules for transforming grammage, unit, prices and quantities of products. For instance, a rule ("ml", "l", 1000) changes the 'old' grammage unit: ml into the new one: l on the basis of the provided relation: 1000ml=1l. As a consequence, for each product which is sold in liters l , the unit price and quantity are calculated.
all	A logical value indicating whether the resulting data frame is to be limited to products with detected grammage. Its default value is TRUE which means that not transformed rows (products) are also returned.

### Value

The function returns the user's data frame with two transformed columns: grammage and unit, and two rescaled columns: prices and quantities. The above-mentioned transformation and rescaling take into consideration the user rules. Recalculated prices and quantities concern grammage units defined as the second parameter in the given rule.

### Examples

```
# Preparing a data set
data<-data_unit(dataU, units=c("g|ml|kg|l"), multiplication="x")
# Normalization of grammage units
data_norm(data, rules=list(c("ml", "l", 1000), c("g", "kg", 1000)))
```

---

data_preparing	<i>Preparing a data set for further data processing or price index calculations</i>
----------------	---

---

### Description

This function returns a prepared data frame based on the user's data set. The resulting data frame is ready for further data processing (such as data selecting, matching or filtering) and it is also ready for price index calculations (if only it contains required columns).

### Usage

```
data_preparing(
  data,
  time = NULL,
  prices = NULL,
  quantities = NULL,
  prodID = NULL,
  retID = NULL,
  description = NULL,
  codeIN = NULL,
  codeOUT = NULL,
  grammage = NULL,
  unit = NULL,
  additional = c(),
```

```

    zero_prices = FALSE,
    zero_quantities = TRUE
  )

```

### Arguments

<code>data</code>	The user's data frame to be prepared. The user must indicate columns: <code>time</code> (as Date or character type, allowed formats are, eg.: '2020-03' or '2020-12-28'), <code>prices</code> and <code>quantities</code> (as numeric). Optionally, the user may also indicate columns: <code>prodID</code> , <code>codeIN</code> , <code>codeOUT</code> , <code>retID</code> (as numeric, factor or character), <code>description</code> (as character), <code>grammage</code> (as numeric or character), <code>unit</code> (as character) and other columns specified by the additional parameter.
<code>time</code>	A character name of the column which provides transaction dates.
<code>prices</code>	A character name of the column which provides product prices.
<code>quantities</code>	A character name of the column which provides product quantities.
<code>prodID</code>	A character name of the column which provides product IDs. The <code>prodID</code> column should include unique product IDs used for product matching (as numeric or character). It is not obligatory to consider this column while data preparing but it is required while price index calculating (to obtain it, please see <a href="#">data_matching</a> ).
<code>retID</code>	A character name of the column which provides outlet IDs (retailer sale points). The <code>retID</code> column should include unique outlet IDs used for aggregating subindices over outlets. It is not obligatory to consider this column while data preparing but it is required while final price index calculating (to obtain it, please see the <a href="#">final_index</a> function).
<code>description</code>	A character name of the column which provides product descriptions. It is not obligatory to consider this column while data preparing but it is required while product selecting (please see the <a href="#">data_selecting</a> function).
<code>codeIN</code>	A character name of the column which provides internal product codes (from the retailer). It is not obligatory to consider this column while data preparing but it may be required while product matching (please see the <a href="#">data_matching</a> function).
<code>codeOUT</code>	A character name of the column which provides external product codes (e.g. GTIN or SKU). It is not obligatory to consider this column while data preparing but it may be required while product matching (please see the <a href="#">data_matching</a> function).
<code>grammage</code>	A character name of the numeric column which provides the grammage of products
<code>unit</code>	A character name of the column which provides the unit of the grammage of products
<code>additional</code>	A character vector of names of additional columns to be considered while data preparing (records with missing values are deleted).
<code>zero_prices</code>	A logical parameter indicating whether zero prices are to be acceptable.
<code>zero_quantities</code>	A logical parameter indicating whether zero quantities are to be acceptable.

**Value**

The resulting data frame is free from: missing values, negative prices (if `zero_prices` is set to `TRUE`), zero or negative prices (if `zero_prices` is set to `FALSE`), negative quantities (if `zero_quantities` is set to `TRUE`) and zero and negative quantities (if `zero_prices` is set to `FALSE`). As a result, column `time` is set to be `Date` type (in format: 'Year-Month-01'), columns `prices` and `quantities` are set to be numeric. If the column `description` is selected, then it is set to be character type. If columns: `prodID`, `retID`, `codeIN` or `codeOUT` are selected, then they are set to be character type.

**Examples**

```
data_preparing(milk, time="time",prices="prices",quantities="quantities")
data_preparing(dataCOICOP, time="time",
prices="prices",quantities="quantities",additional="coicop6")
```

---

data\_reducing

*Reducing products*

---

**Description**

The function returns a reduced data set, i.e. a data set containing sufficiently numerous matched products in the indicated groups. The input data set (data frame) must contain matched products over time, i.e. it must contain the `prodID` column (as numeric, factor or character), or product descriptions, i.e. it must contain the `description` column (as character).

**Usage**

```
data_reducing(
  data,
  start,
  end,
  type = "prodID",
  minN = 2,
  outlets = FALSE,
  by = c(),
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as <code>Date</code> in format: year-month-day,e.g. '2020-12-01') and, depending on next parameter values, columns: <code>prodID</code> or <code>description</code> , and <code>retID</code> .
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".

type	This parameter indicates whether group counts are determined by different matched prodIDs (in which case the parameter has the value 'prodID') or different matched descriptions (in which case the parameter has the value 'description').
minN	This parameter determines the minimum size of matched products in groups.
outlets	This parameter determines whether grouping is to be done for each outlet separately. If so (if it is TRUE), the data set must contain a column identifying the outlets (retID).
by	This parameter specifies the name of the grouping column (as character).
interval	A logical value indicating whether the reducing process concerns only two periods defined by start and end parameters (then the interval is set to FALSE) or whether that function is to reduce products sold during the whole time interval <start, end>.

### Value

The function returns a reduced data set, i.e. a data set containing sufficiently numerous matched products in the indicated groups. For each product group created and for selected periods, the procedure checks that the count of identical prodIDs (or identical product descriptions, which does not necessarily mean the same thing) is at least equal to minN. If it is not, such products are eliminated from the data set. The function performs the check either only for the base and current period (in which case the interval parameter is FALSE) or also for all intermediate months (in which case the interval parameter is TRUE). If the user wants to perform this check for each outlet separately, then the outlets parameter should be set to TRUE.

### Examples

```
data_reducing(sugar, start="2018-12", end="2019-12",by="description", minN=5)
```

---

data_selecting	<i>Selecting products from the user's data set for further price index calculations</i>
----------------	---

---

### Description

The function returns a subset of the user's data set obtained by selection based on keywords and phrases.

### Usage

```
data_selecting(
  data,
  include = c(),
  must = c(),
  exclude = c(),
  sensitivity = FALSE,
  coicop = NULL
)
```

**Arguments**

data	The user's data frame. It must contain a column description (as character).
include	A vector consisting of words and phrases. The function reduces the data set to one in which the description column contains any of these values.
must	A vector consisting of words and phrases. The function reduces the data set to one in which the description column contains each of these values.
exclude	A vector consisting of words and phrases. The function reduces the data set to one in which the description column does not contain any of these values.
sensitivity	A logical parameter indicating whether sensitivity to lowercase and uppercase letters is taken into consideration (if yes, its value is TRUE).
coicop	An optional parameter indicating a value for an additional column coicop which is added to the resulting data frame

**Value**

The function returns a subset of the user's data set obtained by selection based on keywords and phrases defined by parameters: `include`, `must` and `exclude` (an additional column `coicop` is optional). Providing values of these parameters, please remember that the procedure distinguishes between uppercase and lowercase letters only when `sensitivity` is set to TRUE.

**Examples**

```
data_selecting(milk, include=c("milk"), must=c("UHT"))
data_selecting(milk, must=c("milk"), exclude=c("past"))
```

---

data\_unit

*Providing information about the grammage and unit of products*

---

**Description**

The function returns the grammage and unit of products as two additional columns.

**Usage**

```
data_unit(data = data.frame(), units = c("g|ml|kg|l"), multiplication = "x")
```

**Arguments**

data	The user's data frame. The data frame must contain the description column (as character).
units	Units of products which are to be detected (e.g. "ml kg")
multiplication	A sign of the multiplication used in product descriptions (e.g. "x")

**Value**

The function returns the user's data frame with two additional columns: `grammage` and `unit`. The values of these columns are extracted from product descriptions on the basis of provided units. Please note, that the function takes into consideration a sign of the multiplication, e.g. if the product description contains: '2x50 g', we obtain: `grammage: 100` and `unit: g` for that product (for multiplication set to 'x').

**Examples**

```
data_unit(dataU, units=c("g|ml|kg|l"), multiplication="x")
```

---

 davies

---

*Calculating the bilateral Davies price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral Davies price index.

**Usage**

```
davies(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to <code>FALSE</code> ) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to <code>TRUE</code> ).

**Value**

The function returns a value (or vector of values) of the bilateral Davies price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
davies(sugar, start="2018-12", end="2019-12")
davies(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

dikhanov

*Calculating the unweighted Dikhanov price index*

---

## Description

This function returns a value (or vector of values) of the unweighted bilateral Dikhanov price index.

## Usage

```
dikhanov(data, start, end, interval = FALSE)
```

## Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

## Value

The function returns a value (or vector of values) of the unweighted bilateral Dikhanov price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function). This function returns values identical to those of the BMW and YBMD indices (three different names for this index are used in the literature).

## Examples

```
dikhanov(sugar, start="2018-12", end="2019-12")
dikhanov(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

dissimilarity	<i>Calculating the relative price and/or quantity dissimilarity measure between periods</i>
---------------	---

---

## Description

This function returns a value of the relative price and/or quantity dissimilarity measure.

## Usage

```
dissimilarity(data, period1, period2, type = "p")
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
period1	The first period (as character) limited to the year and month, e.g. '2019-03'.
period2	The second period (as character) limited to the year and month, e.g. '2019-04'.
type	The parameter indicates what type of dissimilarity measure is to be calculated. Possible values of the type parameter are: p (for the price dissimilarity measure calculation), q (for the quantity dissimilarity measure calculation) or pq (for the dSPQ measure calculation, i.e. the measure of relative price and quantity dissimilarity - see References).

## Value

This function returns a value of the relative price (dSP) and/or quantity (dSQ) dissimilarity measure. In a special case, when the type parameter is set to pq, the function provides the value of dSPQ measure (the relative price and quantity dissimilarity measure calculated as min(dSP,dSQ)).

## References

Diewert, E. (2020). *The Chain Drift Problem and Multilateral Indexes*. Chapter 6 in: Consumer Price Index Theory (draft)

## Examples

```
dissimilarity(milk, period1="2018-12",period2="2019-12",type="q")
dissimilarity(milk, period1="2018-12",period2="2019-12",type="pq")
```

---

dissimilarity_fig	<i>Presenting the relative price and/or quantity dissimilarity measure over time</i>
-------------------	--

---

## Description

This function presents values of the relative price and/or quantity dissimilarity measure over time.

## Usage

```
dissimilarity_fig(
  data,
  start,
  end,
  type = "p",
  benchmark = "end",
  figure = TRUE,
  date_breaks = "1 month"
)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. '2019-03'.
end	The research period (as character) limited to the year and month, e.g. '2019-07'.
type	The parameter indicates what type of dissimilarity measure is to be calculated. Possible values of the type parameter are: p (for the price dissimilarity measure calculation), q (for the quantity dissimilarity measure calculation) or pq (for the DSPQ measure calculation, i.e. the measure of relative price and quantity dissimilarity - see References).
benchmark	The benchmark period (as character) limited to the year and month, e.g. '2019-07'.

figure	A logical parameter indicating the resulting object. If it is TRUE, the function presents the above-mentioned dissimilarities over time via a figure. Otherwise, the function returns a dataframe.
date_breaks	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".

### Value

This function presents values of the relative price and/or quantity dissimilarity measure over time. The user can choose a benchmark period (defined by benchmark) and the type of dissimilarity measure is to be calculated (defined by type). The obtained results of dissimilarities over time can be presented in a dataframe form or via a figure (the default value of figure is TRUE, which results in a figure).

### Examples

```
dissimilarity_fig(milk, start="2018-12",end="2019-12",type="q",figure=FALSE)
dissimilarity_fig(milk, start="2018-12",end="2019-12",type="pq",benchmark="start")
```

---

drobisch

*Calculating the bilateral Drobisch price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Drobisch price index.

### Usage

```
drobisch(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start,end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Drobisch price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

drobisch(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 dutot

---

*Calculating the unweighted Dutot price index*

---

**Description**

This function returns a value (or vector of values) of the unweighted bilateral Dutot price index.

**Usage**

```
dutot(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the unweighted bilateral Dutot price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
dutot(sugar, start="2018-12", end="2019-12")
dutot(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 elasticity

*Calculating the elasticity of substitution*

---

**Description**

This function returns a value of the elasticity of substitution

**Usage**

```
elasticity(
  data,
  start,
  end,
  method = "lm",
  left = -10,
  right = 10,
  precision = 1e-06
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".

end	The research period (as character) limited to the year and month, e.g. "2020-04".
method	The index formula for which the CES index will be equated to calculate the elasticity. Acceptable options are lm, f, t, w and sv.
left	The beginning of an interval for estimation of the elasticity of substitution (its default value is -10).
right	The end of an interval for estimation of the elasticity of substitution (its default value is 10).
precision	The precision of estimation (a 'stop' condition for the procedure). A default value of this parameter is 0.000001.

### Value

This function returns a value of the elasticity of substitution. If the method parameter is set to lm, the procedure of estimation solves the equation:  $LM(\sigma) - CW(\sigma) = 0$  numerically, where LM denotes the Lloyd-Moulton price index, the CW denotes a current weight counterpart of the Lloyd-Moulton price index, and  $\sigma$  is the elasticity of substitution parameter, which is estimated. If the method parameter is set to f, the Fisher price index formula is used instead of the CW price index. If the method parameter is set to t, the Tornqvist price index formula is used instead of the CW price index. If the method parameter is set to w, the Walsh price index formula is used instead of the CW price index. If the method parameter is set to sv, the Sato-Vartia price index formula is used instead of the CW price index. The procedure continues until the absolute value of this difference is greater than the value of the 'precision' parameter.

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

### Examples

```
elasticity(coffee, start = "2018-12", end = "2019-01")
elasticity(coffee, start = "2018-12", end = "2019-01", method = "f")
elasticity(coffee, start = "2018-12", end = "2019-01", method = "sv")
```

---

elasticity\_fig

*Presenting elasticities of substitution for time interval*

---

### Description

The function provides a data frame or a figure presenting elasticities of substitution calculated for time interval.

**Usage**

```

elasticity_fig(
  data,
  start,
  end,
  method = c("lm"),
  fixedbase = TRUE,
  figure = TRUE,
  date_breaks = "1 month",
  names = c(),
  left = -10,
  right = 10,
  precision = 1e-06
)

```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>method</code>	A vector indicating index formulas for which the CES index will be equated to calculate the elasticity. Acceptable options are <code>lm</code> , <code>f</code> , <code>t</code> , <code>w</code> and <code>sv</code> or their combinations.
<code>fixedbase</code>	A logical parameter indicating whether the procedure is to work for subsequent months from the considered time interval ( <code>fixedbase=FALSE</code> ). Otherwise the period defined by <code>start</code> plays a role of fixed base month ( <code>fixedbase=TRUE</code> )
<code>figure</code>	A logical parameter indicating whether the function returns a figure ( <code>TRUE</code> ) or a data frame ( <code>FALSE</code> ) with values of elasticity of substitution.
<code>date_breaks</code>	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".
<code>names</code>	A character string indicating names of indices used for elasticity approximation (see the <code>method</code> parameter).
<code>left</code>	The beginning of an interval for estimation of each elasticity of substitution (its default value is -10)
<code>right</code>	The end of an interval for estimation of each elasticity of substitution (its default value is 10)
<code>precision</code>	The precision of estimation (a 'stop' condition for the procedure). A default value of this parameter is 0.000001.

**Value**

The function provides a data frame or a figure presenting elasticities of substitution calculated for time interval (see the `figure` parameter). The elasticities of substitution can be calculated for

subsequent months or for a fixed base month (see the `start` parameter) and rest of months from the given time interval (it depends on the `fixedbase` parameter). The above-mentioned parameters for compared months are calculated by using the elasticity function.

## References

de Haan, J., Balk, B.M., Hansen, C.B. (2010). *Retrospective Approximations of Superlative Price Indexes for Years Where Expenditure Data Is Unavailable*. In: Biggeri, L., Ferrari, G. (eds) Price Indexes in Time and Space. Contributions to Statistics. Physica-Verlag HD.

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

## Examples

```
elasticity_fig (milk,start="2018-12",end="2019-04",figure=TRUE,
method=c("lm","f"),names=c("LM","Fisher"))
elasticity_fig (milk,start="2018-12",end="2019-06",figure=FALSE)
```

---

expenditures	<i>Providing expenditures of sold products</i>
--------------	--

---

## Description

The function returns expenditures of sold products with given IDs.

## Usage

```
expenditures(data, period, set = c(), ID = FALSE)
```

## Arguments

<code>data</code>	The user's data frame. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character) with unique product IDs.
<code>period</code>	The time period (as character) limited to the year and month, e.g. "2019-03".
<code>set</code>	The set of unique product IDs to be used for determining expenditures of sold products (see also <a href="#">data_matching</a> ). If the set is empty, the function returns quantities of all products being available in period.
<code>ID</code>	A logical parameter indicating whether a data frame with <code>prodIDs</code> and <code>quantities</code> should be returned.

## Value

The function analyzes the user's data frame and returns expenditures of products with given ID and being sold in the time period indicated by the `period` parameter. Please note that the function returns the expenditure values for sorted `prodIDs` and in the absence of a given `prodID` in the data set, the function returns nothing (it does not return zero). If the `ID` parameter is set to `TRUE` then the function returns a data frame with columns: `by` (IDs of products) and `expend` (expenditures of products).

**Examples**

```

expenditures(milk, period="2019-06")
expenditures(milk, period="2019-12", set=c(400032, 82919), ID=TRUE)

```

---

final_index	<i>A general function to compute a final price index</i>
-------------	--

---

**Description**

This function returns a value (or values) of the selected final price index for the selected type of aggregation of partial results.

**Usage**

```

final_index(
  data = data.frame(),
  start = c(),
  end = c(),
  formula = c(),
  window = c(),
  splice = c(),
  base = c(),
  sigma = c(),
  r = c(),
  outlets = FALSE,
  groups = FALSE,
  by = c(),
  aggr = "fisher",
  interval = FALSE
)

```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). A column retID (as numeric, factor or character) is also essential if the aggregation over outlets is considered. A column with grouping variable (as numeric, factor or character - indicated by the by parameter) is essential if the aggregation over product subgroups is considered.
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
formula	The character string indicating the price index formula is to be calculated. To see available options please use the link: <a href="#">PriceIndices</a> .
window	The length of the time window if the multilateral index is selected (as positive integer: typically multilateral methods are based on the 13-month time window).

splice	A character string indicating the splicing method (if the multilateral splicing index is selected). Available options are: "movement", "window", "half", "mean" and their additional variants: "window_published", "half_published" and "mean_published".
base	The prior period used in the Young- or Lowe-type price indices (as character) limited to the year and month, e.g. "2020-01".
sigma	The elasticity of substitution parameter used in the Lloyed-Moulton, AG Mean or GEKS-LM indices (as numeric).
r	The non-zero parameter used in the quadratic mean of order r quantity / price index or in the GEKS-QM index (as numeric).
outlets	A logical parameter indicating whether the aggregation over outlets (defined by retID column) should be done.
groups	A logical parameter indicating whether the aggregation over product subgroups (indicated by 'by' parameter) should be done.
by	A character string which indicates a column name for creating product subgroups.
aggr	The formula used for aggregating partial index results (available values are: "arithmetic", "geometric", "laspeyres", "paasche", "fisher", "tornqvist").
interval	A logical value indicating whether the function is to provide price indices comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be presented (the fixed base month is defined by start).

### Value

This general function returns a value or values of the selected final price index for the selected type of aggregation of partial results. If the interval parameter is set to TRUE, then it returns a data frame where its first column indicates dates and the remaining columns show corresponding values of all selected price indices.

### Examples

```
final_index(coffee, start = "2018-12", end = "2019-12",
            formula = "fisher", groups = TRUE, outlets = FALSE,
            aggr = "tornqvist", by = "description")
final_index(milk, start = "2018-12", end = "2019-12",
            formula = "fisher", groups = TRUE, outlets = TRUE,
            aggr = "laspeyres", by = "description",
            interval = TRUE)
```

---

fisher

*Calculating the bilateral Fisher price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Fisher price index.

**Usage**

```
fisher(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Fisher price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

fisher(sugar, start="2018-12", end="2019-12")
fisher(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 geary\_khamis

---

*Calculating the bilateral Geary-Khamis price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral Geary-Khamis price index.

**Usage**

```
geary_khamis(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Geary-Khamis price index depending on the interval parameter (please use [gk](#) function to calculate the multilateral Geary-Khamis price index). If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
geary_khamis(sugar, start="2018-12", end="2019-12")
geary_khamis(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 gekS

*Calculating the multilateral GEKS price index*

---

**Description**

This function returns a value of the multilateral GEKS price index (to be more precise: the GEKS index based on the Fisher formula).

**Usage**

```
geks(data, start, end, wstart = start, window = 13)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral GEKS price index (to be more precise: the GEKS index based on the Fisher formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geks(milk, start="2018-12", end="2019-12")
```

---

geksaqi *Calculating the multilateral GEKS-AQI price index*

---

### Description

This function returns a value of the multilateral GEKS-AQI price index (to be more precise: the GEKS index based on the asynchronous quality adjusted price index formula).

### Usage

```
geksaqi(data, start, end, wstart = start, window = 13)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral GEKS-AQI price index (to be more precise: the GEKS index based on the asynchronous quality adjusted price index formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
gekساqi(milk, start="2019-01", end="2019-08", window=10)
gekساqi(milk, start="2018-12", end="2019-12")
```

---

gekساqi_fbew	<i>Extending the multilateral GEKS-AQI price index by using the FBEW method.</i>
--------------	--

---

**Description**

This function returns a value of the multilateral GEKS-AQI price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
gekساqi_fbew(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral GEKS-AQI price index (the GEKS index based on the asynchronous quality adjusted price index formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

geksaqi_fbmw	<i>Extending the multilateral GEKS-AQI price index by using the FBMW method.</i>
--------------	--

---

## Description

This function returns a value of the multilateral GEKS-AQI price index extended by using the FBMW (Fixed Base Moving Window) method.

## Usage

```
geksaqi_fbmw(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral GEKS-AQI price index (the GEKS index based on the asynchronous quality adjusted price index formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksaqi_fbmw(milk, start="2019-12", end="2020-04")
```

---

geksaqi_splice	<i>Extending the multilateral GEKS-AQI price index by using window splicing methods.</i>
----------------	--

---

## Description

This function returns a value (or values) of the multilateral GEKS-AQI price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

## Usage

```
geksaqi_splice(  
  data,  
  start,  
  end,  
  window = 13,  
  splice = "movement",  
  interval = FALSE  
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window","half","mean","window_published","half_published","mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the multilateral GEKS-AQI price index (the GEKS index based on the asynchronous quality adjusted price index formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

*Calculating the multilateral GEKS-AQU price index*

---

## Description

This function returns a value of the multilateral GEKS-AQU price index (to be more precise: the GEKS index based on the asynchronous quality adjusted unit value formula).

## Usage

```
geksequ(data, start, end, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

## Value

This function returns a value of the multilateral GEKS-AQU price index (to be more precise: the GEKS index based on the asynchronous quality adjusted unit value formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geksaqu_splice	<i>Extending the multilateral GEKS-AQU price index by using window splicing methods.</i>
----------------	--

---

**Description**

This function returns a value (or values) of the multilateral GEKS-AQU price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
geksequ_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>splice</code>	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
<code>interval</code>	A logical value indicating whether the function is to provide the price index comparing the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by <code>start</code> ).

**Value**

This function returns a value or values (depending on `interval` parameter) of the multilateral GEKS-AQU price index (the GEKS index based on the asynchronous quality adjusted unit value formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksgaqi_splice(milk, start="2018-12", end="2020-02", splice="half")
```

---

geksgaqi

*Calculating the multilateral GEKS-GAQI price index*

---

## Description

This function returns a value of the multilateral GEKS-GAQI price index (to be more precise: the GEKS index based on the geometric asynchronous quality adjusted price index formula).

## Usage

```
geksgaqi(data, start, end, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral GEKS-GAQI price index (to be more precise: the GEKS index based on the geometric asynchronous quality adjusted price index formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
geksgaqi(milk, start="2019-01", end="2019-08", window=10)
geksgaqi(milk, start="2018-12", end="2019-12")
```

---

geksgaqi_fbew	<i>Extending the multilateral GEKS-GAQI price index by using the FBEW method.</i>
---------------	---

---

**Description**

This function returns a value of the multilateral GEKS-GAQI price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
geksgaqi_fbew(data, start, end)
```

**Arguments**

- |                    |  |
|--------------------|--|
| <code>data</code>  | The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). |
| <code>start</code> | The base period (as character) limited to the year and month, e.g. "2019-12".  |
| <code>end</code>   | The research period (as character) limited to the year and month, e.g. "2020-04".  |

## Value

This function returns a value of the multilateral GEKS-GAQI price index (the GEKS index based on the geometric asynchronous quality adjusted price index formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the `start` parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

geksgaqi_fbmw	<i>Extending the multilateral GEKS-GAQI price index by using the FBMW method.</i>
---------------	---

---

## Description

This function returns a value of the multilateral GEKS-GAQI price index extended by using the FBMW (Fixed Base Moving Window) method.

## Usage

```
geksgaqi_fbmw(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral GEKS-GAQI price index (the GEKS index based on the geometric asynchronous quality adjusted price index formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

geksgaqi_splice	<i>Extending the multilateral GEKS-GAQI price index by using window splicing methods.</i>
-----------------	---

---

**Description**

This function returns a value (or values) of the multilateral GEKS-GAQI price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
geksgaqi_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>splice</code>	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
<code>interval</code>	A logical value indicating whether the function is to provide the price index comparing the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by <code>start</code> ).

**Value**

This function returns a value or values (depending on `interval` parameter) of the multilateral GEKS-GAQI price index (the GEKS index based on the geometric asynchronous quality adjusted price index formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geksgl_splice	<i>Extending the multilateral GEKS-GL price index by using window splicing methods.</i>
---------------	---

---

**Description**

This function returns a value (or values) of the multilateral GEKS-GL price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
geksgl_splice(  
  data,  
  start,  
  end,  
  window = 13,  
  splice = "movement",  
  interval = FALSE  
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the multilateral GEKS-GL price index (the GEKS index based on the geometric Laspeyres formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

 gekseqm

*Calculating the multilateral GEKS-IQM price index*

---

**Description**

This function returns a value of the multilateral GEKS-IQM price index (to be more precise: the GEKS index based on the implicit quadratic mean of order  $r$  price index IQMp).

**Usage**

```
gekseqm(data, start, end, r = 2, wstart = start, window = 13)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>r</code>	The real and non-zero parameter used in the implicit quadratic mean of order <code>r</code> price index.
<code>wstart</code>	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral GEKS-IQM price index (to be more precise: the GEKS index based on the the implicit quadratic mean of order `r` price index IQMp) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
gekSIQM(milk, start="2019-01", end="2019-08", window=10)
gekSIQM(milk, start="2018-12", end="2019-12", r=1.6)
```

---

geksiqm_fbew	<i>Extending the multilateral GEKS-IQM price index by using the FBEW method.</i>
--------------	--

---

### Description

This function returns a value of the multilateral GEKS-IQM price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

### Usage

```
geksiqm_fbew(data, start, end, r)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter used in the implicit quadratic mean of order r price index.

### Value

This function returns a value of the multilateral GEKS-IQM price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

gekseqm_fbmw	<i>Extending the multilateral GEKS-IQM price index by using the FBMW method.</i>
--------------	--

---

**Description**

This function returns a value of the multilateral GEKS-IQM price index extended by using the FBMW (Fixed Base Moving Window) method.

**Usage**

```
gekseqm_fbmw(data, start, end, r)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter used in the implicit quadratic mean of order r price index.

**Value**

This function returns a value of the multilateral GEKS-IQM price index extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

gekspqm_fbmw(milk, start="2019-12", end="2020-04", r=1.6)
```

---

gekspqm_splice	<i>Extending the multilateral GEKS-IQM price index by using window splicing methods.</i>
----------------	--

---

**Description**

This function returns a value (or values) of the multilateral GEKS-IQM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
gekspqm_splice(
  data,
  start,
  end,
  r = 2,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter used in the implicit quadratic mean of order r price index.
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the multilateral GEKS-IQM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

```

---

geksj	<i>Calculating the multilateral GEKS price index based on the Jevons formula (typical notation: GEKS-J)</i>
-------	---

---

**Description**

This function returns a value of the multilateral GEKS-J price index (to be more precise: the GEKS index based on the Jevons formula).

**Usage**

```
geksj(data, start, end, wstart = start, window = 13)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). A column quantities is needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral GEKS-J price index (to be more precise: the GEKS index based on the Jevons formula) which considers the time window defined by wstart and window parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geksj_fbmw	<i>Extending the multilateral GEKS-J price index by using the FBMW method.</i>
------------	--

---

### Description

This function returns a value of the multilateral GEKS-J price index (i.e. the GEKS price index based on the Jevons formula) extended by using the FBMW (Fixed Base Moving Window) method.

### Usage

```
geksj_fbmw(data, start, end)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). A column quantities is needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function returns a value of the multilateral GEKS-J price index (i.e. the GEKS price index based on the Jevons formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geksl(milk, start="2018-12", end="2019-12")
```

---

gekslm *Calculating the multilateral GEKS-LM price index*

---

### Description

This function returns a value of the multilateral GEKS-LM price index (to be more precise: the GEKS index based on the Lloyd-Moulton price index).

### Usage

```
gekslm(data, start, end, sigma = 0.7, wstart = start, window = 13)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
sigma	The elasticity of substitution (a parameter used in the Lloyd-Moulton index formula).
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral GEKS-LM price index (to be more precise: the GEKS index based on the Lloyd-Moulton price index) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

## Description

This function returns a value of the multilateral GEKS-LM price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

## Usage

```
gekslm_fbew(data, start, end, sigma)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
sigma	The elasticity of substitution (a parameter used in the Lloyd-Moulton index formula)..

## Value

This function returns a value of the multilateral GEKS-LM price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
geksqlm_fbmw(milk, start="2019-12", end="2020-04", r=1.6)
```

---

geksqlm_splice	<i>Extending the multilateral GEKS-LM price index by using window splicing methods.</i>
----------------	---

---

**Description**

This function returns a value (or values) of the multilateral GEKS-LM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
geksqlm_splice(  
  data,  
  start,  
  end,
```

```

    sigma = 0.7,
    window = 13,
    splice = "movement",
    interval = FALSE
  )

```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
sigma	The elasticity of substitution (a parameter used in the Lloyd-Moulton index formula).
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

### Value

This function returns a value or values (depending on interval parameter) of the multilateral GEKS-LM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksl_splice(milk, start="2018-12", end="2020-02",splice="half")
```

---

geksqm

*Calculating the multilateral GEKS-QM price index*

---

## Description

This function returns a value of the multilateral GEKS-QM price index (to be more precise: the GEKS index based on the quadratic mean of order  $r$  price index QMp).

## Usage

```
geksqm(data, start, end, r = 2, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter used in the implicit quadratic mean of order $r$ price index.
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral GEKS-QM price index (to be more precise: the GEKS index based on the the quadratic mean of order  $r$  price index QMp) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---------------	---

---

### Description

This function returns a value (or values) of the multilateral GEKS-QM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

### Usage

```
geksqm_splice(  
  data,  
  start,  
  end,
```

```

    r = 2,
    window = 13,
    splice = "movement",
    interval = FALSE
  )

```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>r</code>	The real and non-zero parameter used in the implicit quadratic mean of order <code>r</code> price index.
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>splice</code>	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
<code>interval</code>	A logical value indicating whether the function is to provide the price index comparing the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by <code>start</code> ).

### Value

This function returns a value or values (depending on `interval` parameter) of the multilateral GEKS-QM price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksw(milk, start="2018-12", end="2020-02", r=0.8, splice="half")
```

---

geksw	<i>Calculating the multilateral GEKS price index based on the Walsh formula (GEKS-W)</i>
-------	--

---

## Description

This function returns a value of the multilateral GEKS-W price index, i.e. the GEKS price index based on the superlative Walsh index formula.

## Usage

```
geksw(data, start, end, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

## Value

This function returns a value of the multilateral GEKS-W price index (to be more precise: the GEKS index based on the Walsh formula) which considers the time window defined by wstart and window parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksw(milk, start="2019-01", end="2019-08", window=10)
geksw(milk, start="2018-12", end="2019-12")
```

---

geksw_fbew	<i>Extending the multilateral GEKS-W price index by using the FBEW method.</i>
------------	--

---

## Description

This function returns a value of the multilateral GEKS-W price index (GEKS based on the Walsh formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

## Usage

```
geksw_fbew(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral GEKS-W price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
geksw_fbmw(milk, start="2018-12", end="2019-08")
```

---

geksw_fbmw	<i>Extending the multilateral GEKS-W price index by using the FBMW method.</i>
------------	--

---

## Description

This function returns a value of the multilateral GEKS-W price index (GEKS based on the Walsh formula) extended by using the FBMW (Fixed Base Moving Window) method.

## Usage

```
geksw_fbmw(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral GEKS-W price index extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

geksw_splice	<i>Extending the multilateral GEKS-W price index by using window splicing methods.</i>
--------------	--

---

## Description

This function returns a value (or values) of the multilateral GEKS-W price index (GEKS based on the Walsh formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

## Usage

```
geksw_splice(  
  data,  
  start,  
  end,  
  window = 13,  
  splice = "movement",  
  interval = FALSE  
)
```

## Arguments

- |       |   |
|-------|---|
| data  | The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). |
| start | The base period (as character) limited to the year and month, e.g. "2019-12".   |

end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

### Value

This function returns a value or values (depending on interval parameter) of the multilateral GEKS-W price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geks_splice(milk, start="2018-12", end="2020-02", splice="half")
```

---

generate

*Generating an artificial scanner dataset*

---

## Description

This function provides artificial scanner datasets where prices and quantities are lognormally distributed.

## Usage

```
generate(  
  pmi = c(),  
  psigma = c(),  
  qmi = c(),  
  qsigma = c(),
```

```

prec = c(2, 0),
n = 100,
n0 = 1,
r = 1,
r0 = 1,
start,
days = FALSE
)

```

### Arguments

pmi	A numeric vector indicating mi parameters for lognormally distributed prices from the subsequent months.
psigma	A numeric vector indicating sigma parameters for lognormally distributed prices from the subsequent months.
qmi	A numeric vector indicating mi parameters for lognormally distributed quantities from the subsequent months.
qsigma	A numeric vector indicating sigma parameters for lognormally distributed quantities from the subsequent months.
prec	A two-dimensional numeric vector indicating precision, i.e. the number of decimal places, for presenting prices and quantities.
n	An integer parameter indicating the number of products which are to be generated.
n0	An integer parameter indicating the first (the smallest) prodID.
r	An integer parameter indicating the number of outlets (retailer sale points) for which prices and quantities are to be generated.
r0	n0 An integer parameter indicating the first (the smallest) retID.
start	The first period in the generated data frame (as character) limited to the year and month, e.g. '2019-12'.
days	A logical parameter indicating whether the trading day in a given month is to be randomised. The default value of days is FALSE, which means that each transaction for a given month takes place on the first day of the month.

### Value

This function returns an artificial scanner dataset where prices and quantities are lognormally distributed. The characteristics for these lognormal distributions are set by pmi, psigma, qmi and qsigma parameters. This function works for a fixed number of products and outlets (see n and r parameters). The generated dataset is ready for further price index calculations.

Sulewski, P., Białek, J. (2022). *Probability Distribution Modelling of Scanner Prices and Relative Prices*. Statistika – Statistics and Economy Journal, Vol. 3/2022, 282-298, Czech Statistical Office, Prague.

**Examples**

```
generate(pmi=c(1.02,1.03,1.04),psigma=c(0.05,0.09,0.02),qmi=c(3,4,4),
         qsigma=c(0.1,0.1,0.15),start="2020-01",days=TRUE)
generate(pmi=c(1.02,1.03,1.04),psigma=c(0.05,0.09,0.02),qmi=c(6,6,7),
         qsigma=c(0.1,0.1,0.15),start="2020-01",n=1000,n0=132578,r=10)
```

generate\_CES

*Generating an artificial scanner dataset in the CES model***Description**

This function provides artificial scanner datasets where prices are lognormally distributed and quantities are obtained under a CES utility.

**Usage**

```
generate_CES(
  pmi = c(),
  psigma = c(),
  prec = 2,
  elasticity = 0.7,
  S = 1000,
  alfa = c(),
  n = 100,
  n0 = 1,
  r = 1,
  r0 = 1,
  start,
  days = FALSE
)
```

**Arguments**

pmi	A numeric vector indicating $\mu_i$ parameters for lognormally distributed prices from the subsequent months.
psigma	A numeric vector indicating $\sigma_i$ parameters for lognormally distributed prices from the subsequent months.
prec	A numeric value indicating precision, i.e. the number of decimal places, for generating prices.
elasticity	The elasticity of substitution. The default value is 0.7.
S	Sum of spending. The default value is 1000.
alfa	A numeric vector indicating positive weights that reflect the consumer preferences. By default, this vector is randomized based on a uniform distribution.
n	An integer parameter indicating the number of products which are to be generated.

n0	An integer parameter indicating the first (the smallest) prodID.
r	An integer parameter indicating the number of outlets (retailer sale points) for which prices and quantities are to be generated.
r0	n0 An integer parameter indicating the first (the smallest) retID.
start	The first period in the generated data frame (as character) limited to the year and month, e.g. '2019-12'.
days	A logical parameter indicating whether the trading day in a given month is to be randomised. The default value of days is FALSE, which means that each transaction for a given month takes place on the first day of the month.

### Value

This function returns an artificial scanner dataset where prices are lognormally distributed, quantities are calculated under the assumption that consumers have CES (Constant Elasticity of Substitution) preferences and their spending on all products is  $S$ . The characteristics for the lognormal price distribution are set by `pmi` and `psigma` parameters. This function works for a fixed number of products and outlets (see `n` and `r` parameters). The generated dataset is ready for further price index calculations.

### Examples

```
#Generating an artificial dataset (the elasticity of substitution is 1.25)
df<-generate_CES(pmi=c(1.02,1.03),psigma=c(0.04,0.03),
elasticity=1.25,start="2020-01",n=100,days=TRUE)
#Verifying the elasticity of substitution
elasticity(df, start="2020-01",end="2020-02")
```

---

geohybrid

*Calculating the bilateral geohybrid price index*

---

### Description

This function returns a value (or vector of values) of the bilateral geohybrid price index. The geohybrid index was proposed by Bialek (2020) and it uses correlation coefficients between prices and quantities.

### Usage

```
geohybrid(data, start, end, base = start, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>base</code>	The prior period used in the geohybrid price index formula (as character) limited to the year and month, e.g. "2020-01"
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geohybrid price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

 geolaspeyres

*Calculating the bilateral geo-logarithmic Laspeyres price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral geo-logarithmic Laspeyres price index.

**Usage**

```
geolaspeyres(data, start, end, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geo-logarithmic Laspeyres price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

 geolowe

---

*Calculating the bilateral geometric Lowe price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral geometric Lowe price index.

**Usage**

```
geolowe(data, start, end, base = start, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>base</code>	The prior period used in the geometric Lowe price index formula (as character) limited to the year and month, e.g. "2020-01"
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geometric Lowe price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

 geopaasche

---

*Calculating the bilateral geo-logarithmic Paasche price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral geo-logarithmic Paasche price index.

**Usage**

```
geopaasche(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geo-logarithmic Paasche price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

 geowalsh

---

*Calculating the bilateral geometric Walsh price index*

---

**Description**

This function returns a value (or vector of values) of the geometric Walsh price index.

**Usage**

```
geowalsh(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geometric Walsh price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

geowalsh(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 geoyoung

---

*Calculating the bilateral geometric Young price index*

---

**Description**

This function returns a value (or vector of values) of the bilateral geometric Young price index.

**Usage**

```
geoyoung(data, start, end, base = start, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the geometric Young price index formula (as character) limited to the year and month, e.g. "2020-01"
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral geometric Young price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
geoyoung(sugar, start="2019-01", end="2020-01",base="2018-12")
geoyoung(milk, start="2018-12", end="2020-01", interval=TRUE)
```

gk

*Calculating the multilateral Geary-Khamis price index***Description**

This function returns a value of the multilateral Geary-Khamis price index.

**Usage**

```
gk(data, start, end, wstart = start, window = 13)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral Geary-Khamis price index which considers the time window defined by `wstart` and `window` parameters. The Geary-Khamis price index is calculated by using a special iterative algorithm from Chessa (2016). It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
gk(milk, start="2019-01", end="2019-08",window=10)
gk(milk, start="2018-12", end="2019-12")
```

gk\_fbew

---

*Extending the multilateral Geary-Khamis price index by using the FBEW method.*

---

**Description**

This function returns a value of the multilateral Geary-Khamis price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
gk_fbew(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral Geary-Khamis price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

gk_fbew(milk, start="2018-12", end="2019-08")
```

---

gk\_fbmw

*Extending the multilateral Geary-Khamis price index by using the FBMW method.*

---

**Description**

This function returns a value of the multilateral Geary-Khamis price index extended by using the FBMW (Fixed Base Moving Window) method.

**Usage**

```
gk_fbmw(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral Geary-Khamis price index extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

gk_splice	<i>Extending the multilateral Geary-Khamis price index by using window splicing methods.</i>
-----------	--

---

**Description**

This function returns a value (or values) of the multilateral Geary-Khamis price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
gk_splice(data, start, end, window = 13, splice = "movement", interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the multilateral Geary-Khamis price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```
gk_splice(milk, start="2018-12", end="2020-02",splice="half")
```

---

 harmonic

*Calculating the unweighted harmonic price index*

---

**Description**

This function returns a value (or vector of values) of the unweighted "unnamed" harmonic price index.

**Usage**

```
harmonic(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the unweighted bilateral harmonic price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

Von der Lippe, P. (2007). *Index Theory and Price Statistics*. Peter Lang: Berlin, Germany.  
 (2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```

harmonic(sugar, start="2018-12", end="2019-12")
harmonic(milk, start="2018-12", end="2020-01", interval=TRUE)

```

hlc

*Calculating the bilateral harmonic log-change (HLC) price index***Description**

This function returns a value (or vector of values) of the bilateral harmonic log-change price index.

**Usage**

```
hlc(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral harmonic log-change price index (HLC), i.e., the log-change index constructed using weights equal to the harmonic mean of expenditure shares (rather than the arithmetic mean used in the Törnqvist index). If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```

hlc(sugar, start="2018-12", end="2019-12")
hlc(milk, start="2018-12", end="2020-01", interval=TRUE)

```

---

hybrid	<i>Calculating the bilateral hybrid price index</i>
--------	---

---

### Description

This function returns a value (or a vector of values) of the bilateral hybrid price index. The hybrid index was proposed by Bialek (2020) and it uses correlation coefficients between prices and quantities.

### Usage

```
hybrid(data, start, end, base = start, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. '2020-03'.
end	The research period (as character) limited to the year and month, e.g. '2020-04'.
base	The prior period used in the hybrid price index formula (as character) limited to the year and month, e.g. '2020-01'.
interval	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

### Value

The function returns a value (or a vector of values) of the bilateral hybrid price index depending on the `interval` parameter. If the `interval` parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### References

Bialek, J. (2020). *Proposition of a Hybrid Price Index Formula for the Consumer Price Index Measurement*. *Equilibrium. Quarterly Journal of Economics and Economic Policy*, 15(4), 697-716.

### Examples

```
hybrid(sugar, start="2019-12", end="2020-08", base="2018-12")
hybrid(milk, start="2019-12", end="2020-08", base="2018-12", interval=TRUE)
```

IQMp

*Calculating the implicit quadratic mean of order r price index***Description**

This function returns a value (or vector of values) of the implicit quadratic mean of order r price index.

**Usage**

```
IQMp(data, start, end, r = 2, interval = FALSE)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>r</code>	The real and non-zero parameter.
<code>interval</code>	A logical value indicating whether the function is to compare the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <code>&lt;start, end&gt;</code> are considered and <code>start</code> defines the base period ( <code>interval</code> is set to TRUE).

**Value**

The function returns a value (or vector of values) of the implicit quadratic mean of order r price index - see CPI Manual (2004), Section 17.37, formula 17.32 (page 321).

**References**

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
IQMp(sugar, start="2019-01", end="2020-01")
IQMp(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

---

jevons *Calculating the unweighted Jevons price index*

---

### Description

This function returns a value (or vector of values) of the unweighted bilateral Jevons price index.

### Usage

```
jevons(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the unweighted bilateral Jevons price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

 laspeyres
 

---

---

*Calculating the bilateral Laspeyres price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Laspeyres price index.

### Usage

```
laspeyres(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Laspeyres price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

lehr	<i>Calculating the bilateral Lehr price index</i>
------	---

---

### Description

This function returns a value (or vector of values) of the bilateral Lehr price index.

### Usage

```
lehr(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Lehr price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

lloyd_moulton	<i>Calculating the bilateral Lloyd-Moulton price index</i>
---------------	--

---

### Description

This function returns a value (or vector of values) of the bilateral Lloyd-Moulton price index.

### Usage

```
lloyd_moulton(data, start, end, sigma = 0.7, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
sigma	The elasticity of substitution parameter (as numeric).
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Lloyd-Moulton price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

lowe(milk, start="2018-12", end="2020-01", interval=TRUE)
```

MARS

*Data stratification via the MARS method***Description**

This function groups prodIDs into strata ('products') by balancing two measures: an explained variance (R squared) measure for the 'homogeneity' of prodIDs within products, while the second expresses the degree to which products can be 'matched' over time with respect to a comparison period.

**Usage**

```
MARS(
  data = data.frame(),
  start,
  end,
  attributes = c(),
  n = 3,
  strategy = "two_months"
)
```

**Arguments**

<code>data</code>	The user's data frame with information about products. It must contain attributes: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric), <code>prodID</code> (as numeric or character) and the attributes indicated by the 'attributes' parameter.
<code>start</code>	The base period $\theta$ (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period $t$ (as character) limited to the year and month, e.g. "2020-04".
<code>attributes</code>	A character vector with column names specifying the product attributes.
<code>n</code>	Parameter needed only if <code>last_months</code> strategy is selected. This parameter specifies how many last months are to be taken into account for calculating the average MARS value.
<code>strategy</code>	A variable that determines how to calculate the degree of product match, the degree of homogeneity (the weighted R squared measure) and the final MARS score. Available options are: <code>two_months</code> (only base and current periods are considered, i.e. the MARS score is computed for periods $\theta$ and $t$ ), <code>interval_base</code> (MARS scores are calculated for each pair of periods: (0,1), (0,2), ..., (0,t) and the geometric mean of these values is returned), <code>interval_chain</code> (MARS scores are calculated for each pair of periods: (0,1), (1,2), ..., (t-1,t) and the geometric

mean of these values is returned), `interval_pairs` (MARS scores are calculated for each pair of periods: (a,b) from periods (0,1,2,...,t) and the geometric mean of these values is returned), `last_months` (MARS scores are calculated for each pair of periods: (t-n,t), (t-n+1,2), ... (t-1,t) and the geometric mean of these values is returned).

### Value

This function groups prodIDs into strata ('products') by balancing two measures: an explained variance (R squared) measure for the 'homogeneity' of prodIDs within products, while the second expresses the degree to which products can be 'matched' over time with respect to a comparison period. The resulting product 'match adjusted R squared' (MARS) combines explained variance in product prices with product match over time, so that different stratification schemes can be ranked according to the combined measure. Any combination of attributes is taken into account when creating stratas. For example, for a set of attributes (A, B, C), the stratas created by the following attribute combinations are considered: A, B, C, A-B, A-C, B-C, A-B-C. The function returns a list with the following elements: `scores` (with scores for degrees of product match and product homogeneity, as well as for MARS measure), `best_partition` (with the name of the partition for which the highest indication of the MARS measure was obtained), and `data_MARS` (with a data frame obtained by replacing the original prodIDs with identifiers created based on the selected best partition).

marshall\_edgeworth      *Calculating the bilateral Marshall-Edgeworth price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Marshall-Edgeworth price index.

### Usage

```
marshall_edgeworth(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Marshall-Edgeworth price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
marshall_edgeworth(sugar, start="2018-12", end="2019-12")
marshall_edgeworth(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

matched	<i>Providing values from the indicated column that occur simultaneously in the compared periods or in a given time interval.</i>
---------	--

---

**Description**

The function returns all values from the indicated column (defined by the type parameter) which occur simultaneously in the compared periods or in a given time interval.

**Usage**

```
matched(data, period1, period2, type = "prodID", interval = FALSE)
```

**Arguments**

data	The user's data frame. It must contain a column time (as Date in format: year-month-day, e.g. '2020-12-01') and also a column indicated by the type parameter.
period1	The first period (as character) limited to the year and month, e.g. "2019-03".
period2	The second period (as character) limited to the year and month, e.g. "2019-04".
type	This parameters defines the column which is used in the procedure. Possible values of the type parameter are: retID, prodID, codeIN, codeOUT or description.
interval	A logical parameter indicating whether the procedure is to work for the whole time period between period1 and period2 (then it is TRUE).

**Value**

The function returns all values from the indicated column (defined by the type parameter) which occur simultaneously in the compared periods or in a given time interval. Possible values of the type parameter are: retID, prodID, codeIN, codeOUT or description. If the interval parameter is set to FALSE, then the function compares only periods defined by period1 and period2. Otherwise the whole time period between period1 and period2 is considered.

**Examples**

```
matched(milk, period1="2018-12", period2="2019-12", interval=TRUE)
matched(milk, period1="2018-12", period2="2019-12", type="description")
```

---

 matched\_fig

---

*Providing a time dependent matched\_index() function*

---

**Description**

The function provides a data frame or a figure presenting the `matched_index` function calculated for the column defined by the type parameter and for each month from the considered time interval

**Usage**

```
matched_fig(
  data,
  start,
  end,
  base = "start",
  type = "prodID",
  fixedbase = TRUE,
```

```

    figure = TRUE,
    date_breaks = "1 month"
  )

```

### Arguments

data	The user's data frame. It must contain a column time (as Date in format: year-month-day, e.g. '2020-12-01') and also a column indicated by the type parameter.
start	The beginning of a time interval (as character) limited to the year and month, e.g. "2019-03".
end	The end of a time interval (as character) limited to the year and month, e.g. "2019-04".
base	The base period (as character) for product comparisons. Its possible values are: "start" and "end".
type	This parameter defines the column which is used in the procedure. Possible values of the type parameter are: retID, prodID, codeIN, codeOUT or description.
fixedbase	A logical parameter indicating whether the procedure is to work for subsequent months from the considered time interval (fixedbase=FALSE). Otherwise the period defined by base plays a role of fixed base month (fixedbase=TRUE)
figure	A logical parameter indicating whether the function returns a figure (TRUE) or a data frame (FALSE) with <code>matched_index</code> values.
date_breaks	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".

### Value

The function returns a data frame or a figure presenting the `matched_index` function calculated for the column defined by the `type` parameter and for each month from the considered time interval. The interval is set by `start` and `end` parameters. The returned object (data frame or figure) depends on the value of `figure` parameter. The returned values belong to [0,1].

### Examples

```

matched_fig(milk, start="2018-12", end="2019-12")
matched_fig(milk, start="2018-12", end="2019-12", figure=FALSE)

```

---

matched_index	<i>Providing the ratio of number of matched values from the indicated column to the number of all available values from this column</i>
---------------	---

---

### Description

The function returns a ratio of number of values from the indicated column that occur simultaneously in the compared periods or in a given time interval to the number of all available values from the above-mentioned column (defined by the `type` parameter) at the same time.

**Usage**

```
matched_index(data, period1, period2, type = "prodID", interval = FALSE)
```

**Arguments**

data	The user's data frame. It must contain a column time (as Date in format: year-month-day, e.g. '2020-12-01') and also a column indicated by the type parameter.
period1	The first period (as character) limited to the year and month, e.g. "2019-03".
period2	The second period (as character) limited to the year and month, e.g. "2019-04".
type	This parameter defines the column which is used in the procedure. Possible values of the type parameter are: retID, prodID, codeIN, codeOUT or description.
interval	A logical parameter indicating whether the procedure is to work for the whole time period between period1 and period2 (then it is TRUE).

**Value**

The function returns a ratio of number of values from the indicated column that occur simultaneously in the compared periods or in a given time interval to the number of all available values from the above-mentioned column (defined by the type parameter) at the same time. Possible values of the type parameter are: retID, prodID or description. If the interval parameter is set to FALSE, then the function compares only periods defined by period1 and period2. Otherwise the whole time period between period1 and period2 is considered. The returned value belongs to [0,1].

**Examples**

```
matched_index(milk, period1="2018-12", period2="2019-12", interval=TRUE)
matched_index(milk, period1="2018-12", period2="2019-12", type="retID")
```

---

 mbennet

---

*Calculating the multilateral Bennet price and quantity indicators*

---

**Description**

This function returns the multilateral Bennet price and quantity indicators and optionally also the price and quantity contributions of individual products.

**Usage**

```
mbennet(
  data,
  start,
  end,
  wstart = start,
  matched = FALSE,
```

```

    window = 13,
    interval = FALSE,
    contributions = FALSE,
    prec = 2
  )

```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>wstart</code>	The first period of the time window (as character) limited to the year and month, e.g. "2019-12".
<code>matched</code>	A logical parameter indicating whether the matched sample approach is to be used (if yes, the parameter has the value TRUE).
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>interval</code>	A logical parameter indicating whether calculations are to be made for the whole time interval (TRUE) or no (FALSE).
<code>contributions</code>	A logical parameter indicating whether contributions of individual products are to be displayed. If it is TRUE, then contributions are calculated for the the base period <code>start</code> and the current period <code>end</code> .
<code>prec</code>	A numeric vector indicating precision, i.e. the number of decimal places for presenting results.

### Value

This function returns the multilateral Bennet price and quantity indicators and optionally also the price and quantity contributions of individual products.

### Examples

```

mbennet(milk, "2018-12", "2019-12", matched=TRUE, contributions=TRUE)
mbennet(coffee, start="2018-12", end="2019-03", interval=TRUE)

```

---

milk	<i>A real data set on sold milk</i>
------	-------------------------------------

---

**Description**

A collection of scanner data on the sale of milk in one of Polish supermarkets in the period from December 2018 to August 2020

**Usage**

milk

**Format**

A data frame with 6 columns and 4386 rows. The used variables are as follows:

time - Dates of transactions (Year-Month-Day)

prices - Prices of sold products [PLN]

quantities - Quantities of sold products [liters]

prodID - Unique product codes (data set contains 68 different prodIDs)

retID - Unique codes identifying outlets/retailer sale points (data set contains 5 different retIDs)

description Descriptions of sold milk products (data set contains 6 different product descriptions)

---

mmontgomery	<i>Calculating the multilateral Montgomery price and quantity indicators</i>
-------------	--

---

**Description**

This function returns the multilateral Montgomery price and quantity indicators and optionally also the price and quantity contributions of individual products.

**Usage**

```
mmontgomery(  
  data,  
  start,  
  end,  
  wstart = start,  
  matched = FALSE,  
  window = 13,  
  interval = FALSE,  
  contributions = FALSE,  
  prec = 2  
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The first period of the time window (as character) limited to the year and month, e.g. "2019-12".
matched	A logical parameter indicating whether the matched sample approach is to be used (if yes, the parameter has the value TRUE).
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
interval	A logical parameter indicating whether calculations are to be made for the whole time interval (TRUE) or no (FALSE).
contributions	A logical parameter indicating whether contributions of individual products are to be displayed. If it is TRUE, then contributions are calculated for the the base period start and the current period end.
prec	A numeric vector indicating precision, i.e. the number of decimal places for presenting results.

**Value**

This function returns the multilateral Montgomery price and quantity indicators and optionally also the price and quantity contributions of individual products.

**References**

**Examples**

```
mmontgomery(milk, "2018-12", "2019-12", matched=TRUE, contributions=TRUE)
mmontgomery(coffee, start="2018-12", end="2019-03", interval=TRUE)
```

**Description**

This function returns the Montgomery price and quantity indicators and optionally also the price and quantity contributions of individual products.

**Usage**

```
montgomery(  
  data,  
  start,  
  end,  
  interval = FALSE,  
  matched = FALSE,  
  contributions = FALSE,  
  prec = 2  
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical parameter indicating whether calculations are to be made for the whole time interval (TRUE) or no (FALSE).
matched	A logical parameter indicating whether the matched sample approach is to be used (if yes, the parameter has the value TRUE).
contributions	A logical parameter indicating whether contributions of individual products are to be displayed. If it is TRUE, then contributions are calculated for the the base period start and the current period end.
prec	A numeric vector indicating precision, i.e. the number of decimal places for presenting results.

**Value**

This function returns the Montgomery price and quantity indicators and optionally also the price and quantity contributions of individual products.

## References

Montgomery, J. K., (1929). *Is There a Theoretically Correct Price Index of a Group of Commodities?* Rome, International Institute of Agriculture

## Examples

```
montgomery(milk, "2018-12", "2019-12", matched=TRUE, contributions=TRUE)
montgomery(coffee, start="2018-12", end="2019-03", interval=TRUE)
```

---

m_decomposition	<i>Multiplicative decomposing the GEKS-type indices</i>
-----------------	---

---

## Description

This function returns multiplicative decompositions of the selected GEKS-type indices.

## Usage

```
m_decomposition(
  data,
  start,
  end,
  wstart = start,
  formula = c(),
  window = 13,
  sigma = 0.7,
  index.value = TRUE
)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
formula	A parameter indicating which multilateral formulas are to be decomposed. In the current version of the package, the multiplicative decomposition includes the following GEKS-type indices: GEKS, CCDI, GEKS-W, GEKS-L, GEKS-GL, GEKS-LM, GEKS-AQI, and GEKS-GAQI. Thus, this parameter can take values like: "geks", "ccdi", "geksw", "geksl", "geksgl", "gekslm", "geksgaqi", "geksgaqi".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

sigma	The elasticity of substitution (a parameter used in the Lloyd-Moulton index formula). The default value is 0.7.
index.value	The parameter indicating whether price index values are to be displayed (at the end of the returned multiplicative data frame).

### Value

This function returns a list with three elements: `multiplicative` - a data frame containing multiplicative decompositions of the indicated GEKS-type indices, `normalized` - normalized multiplicative decompositions of the indicated indices (their product is always 1), `impact` - relative impacts of commodities on the price index value (in p.p.).

Białek, J. (2026). *Multiplicative Decompositions of GEKS-type Indices into the Contribution of Individual Commodities*. Journal of Official Statistics, 42(1), 62-91

### Examples

```
m_decomposition(milk, start="2018-12", end="2019-12", formula=c("geks", "ccdi"))$multiplicative
```

---

outlet_check	<i>Reducing outlets</i>
--------------	-------------------------

---

### Description

The general purpose of the function is to determine in what proportion of the retail chain's outlets the number of matched products within the analyzed time interval (or at its boundaries) exceeds a certain minimum specified by the user. The input data set (data frame) must contain matched products over time, i.e. it must contain the `prodID` column (as numeric, factor or character) and the grouping variable (i.e., an optional column) selected via `by` parameter.

### Usage

```
outlet_check(
  data,
  start,
  end,
  by = c(),
  minN = 2,
  threshold = 0.9,
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01') and, depending on next parameter values, columns: <code>prodID</code> or <code>description</code> , and <code>retID</code> .
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>by</code>	This parameter specifies the name of the grouping column (as character). If the user does not specify any column via the <code>by</code> parameter, the outlet reduction will be performed without grouping.
<code>minN</code>	This parameter specifies the required minimum number of matched products present in a single outlet, within the grouping defined via the <code>by</code> parameter and within the specified time interval (or at its boundaries, depending on the <code>interval</code> parameter).
<code>threshold</code>	The lower bound of the acceptable fraction of complete outlets, i.e., outlets in which the number of matched products referred to above is not less than the <code>minN</code> level.
<code>interval</code>	A logical value indicating whether the reducing process concerns only two periods defined by <code>start</code> and <code>end</code> parameters (then the <code>interval</code> is set to <code>FALSE</code> ) or whether that function is to reduce outlets during the whole time interval <code>&lt;start, end&gt;</code> .

**Value**

The function first determines the fraction of outlets (within subsets defined by the grouping column specified by the `by` parameter) that are complete, i.e., those containing at least `minN` matched products. If this fraction exceeds the value specified by `threshold`, a resulting data frame `df` is created consisting only of complete outlets, and the variable `result` is set to `TRUE`. Otherwise, `df` remains the original data, and the variable `result` is set to `FALSE`. The function returns a list consisting of the following elements: `fraction` (indicating the fraction of complete outlets), `result`, and `df`. This function can be used to automatically set the values of the `data` and `outlets` parameters in the `final_index` function.

**Examples**

```
outlet_reduction <-
outlet_check(coffee, start="2018-12", end="2019-12",
minN=3, by="description", interval=TRUE)
outlet_reduction$fraction
outlet_reduction$result
outlet_reduction$df
```

---

paasche	<i>Calculating the bilateral Paasche price index</i>
---------	--

---

## Description

This function returns a value (or vector of values) of the bilateral Paasche price index.

## Usage

```
paasche(data, start, end, interval = FALSE)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

## Value

The function returns a value (or vector of values) of the bilateral Paasche price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
paasche(sugar, start="2018-12", end="2019-12")
paasche(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

 palgrave

*Calculating the bilateral Palgrave price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Palgrave price index.

### Usage

```
palgrave(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Palgrave price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

palgrave(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

pqcor	<i>Providing a correlation coefficient for price and quantity of sold products</i>
-------	--

---

**Description**

The function returns correlation between price and quantity of sold products with given IDs.

**Usage**

```
pqcor(data, period, set = c(), figure = FALSE)
```

**Arguments**

data	The user's data frame. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character) with unique product IDs.
period	The time period (as character) limited to the year and month, e.g. "2019-03".
set	The set of unique product IDs to be used for determining correlation between price and quantity of sold products (see also <a href="#">data_matching</a> ). If the set is empty, the function works for all products being available in period.
figure	A logical parameter indicating whether the function returns a figure (TRUE) or a data frame (FALSE) with correlations between price and quantity of sold products.

**Value**

The function returns Pearson's correlation coefficient between price and quantity of products with given IDs and sold in period.

**Examples**

```
pqcor(milk, period="2019-03")
pqcor(milk, period="2019-03", figure=TRUE)
```

---

pqcor_fig	<i>Providing correlations between price and quantity of sold products</i>
-----------	---

---

**Description**

The function returns Pearson's correlation coefficients between price and quantity of sold products with given IDs.

**Usage**

```
pqcor_fig(data, start, end, figure = TRUE, date_breaks = "1 month", set = c())
```

**Arguments**

<code>data</code>	The user's data frame. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character) with unique product IDs.
<code>start</code>	The beginning of the considered time interval (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The end of the considered time interval (as character) limited to the year and month, e.g. "2020-04".
<code>figure</code>	A logical parameter indicating whether the function returns a figure (TRUE) or a data frame (FALSE) with price-quantity correlations.
<code>date_breaks</code>	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".
<code>set</code>	The set of unique product IDs to be used for determining correlation between prices and quantities of sold products (see also <a href="#">data_matching</a> ). If the set is empty, the function works for all products being available in period.

**Value**

The function returns Pearson's correlation coefficients between price and quantity of products with given IDs and sold in the time interval: `<start, end>`. Correlation coefficients are calculated for each month separately. Results are presented in tabular or graphical form depending on the `figure` parameter.

**Examples**

```
pqcor_fig(milk, start="2018-12", end="2019-12", figure=FALSE)
pqcor_fig(milk, start="2018-12", end="2019-12", figure=TRUE)
```

prices

*Providing prices (unit values) of sold products*

---

#### **Description**

The function returns prices (unit values) of sold products with given IDs.

#### **Usage**

```
prices(data, period, set = c(), ID = FALSE)
```

**Arguments**

data	The user's data frame. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character) with unique product IDs.
period	The time period (as character) limited to the year and month, e.g. "2019-03".
set	The set of unique product IDs to be used for determining prices of sold products (see also <a href="#">data_matching</a> ). If the set is empty, the function returns prices of all products being available in period.
ID	A logical parameter indicating whether a data frame with prodIDs and prices (unit values) should be returned.

**Value**

The function analyzes the user's data frame and returns prices (unit value) of products with given ID and being sold in the time period indicated by the `period` parameter. Please note, that the function returns the price values for sorted prodIDs and in the absence of a given prodID in the data set, the function returns nothing (it does not return zero). If the ID parameter is set to TRUE then the function returns a data frame with columns: `by` (IDs of products) and `uv` (unit values of products).

**Examples**

```
prices(milk, period="2019-06")
prices(milk, period="2019-12", set=c(400032, 82919), ID=TRUE)
```

---

price\_indices

*A general function to compute one or more price indices*

---

**Description**

This function returns a value or values of the selected price indices.

**Usage**

```
price_indices(
  data,
  start,
  end,
  formula = c(),
  window = c(),
  splice = c(),
  base = c(),
  sigma = c(),
  r = c(),
  interval = FALSE,
  names = c()
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also essential even if the selected index is an unweighted formula (unit values are calculated).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
formula	A vector of character strings indicating price index formulas that are to be calculated. To see available options please use the link: <a href="#">PriceIndices</a> .
window	A vector of integers. Each element of the vector defines the length of the time window of the corresponding multilateral index.
splice	A vector of character strings. Each element of the vector indicates the splicing method is to be used for the corresponding multilateral index. Available values of vector elements are: "movement", "window","half","mean" and their additional variants: "window_published", "half_published" and "mean_published".
base	The vector of prior periods used in the Young- or Lowe-type price indices or hybrid/geo hybrid index. Each element of the vector (as character) must be limited to the year and month, e.g. "2020-01".
sigma	The vector of elasticity of substitution parameters used in the Lloyd-Moulton, AG Mean or GEKS-LM indices (as numeric).
r	The vector of non-zero parameters used in the quadratic mean of order r quantity / price index or in the GEKS-QM index (as numeric).
interval	A logical value indicating whether the function is to provide price indices comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be presented (the fixed base month is defined by start).
names	A vector of strings indicating names of indices which are to be used in the resulting data frame.

**Value**

This general function returns a value or values of the selected price indices. If the interval parameter is set to TRUE, then it returns a data frame where its first column indicates dates and the remaining columns show corresponding values of all selected price indices. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
price_indices(milk,
              start="2018-12",end="2019-12",
              formula=c("geks","ccdi","hybrid","fisher",
                        "QMp","young","geksl_fbew"),
              window=c(13,13),
              base=c("2019-03","2019-03"),
```

```

      r=c(3),interval=TRUE)
price_indices(milk,
  start="2018-12",end="2019-12",
  formula=c("geks","ccdi","hybrid","fisher",
  "QMp","young","geksl_fbew"),
  window=c(13,13),
  base=c("2019-03","2019-03"),
  r=c(3),interval=FALSE)

```

---

products	<i>Detecting and summarising available, matched, new and disappearing products.</i>
----------	---

---

### Description

This function detects and summarises available, matched, new as well as disappearing products on the basis of their prodIDs.

### Usage

```
products(data, start, end)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01') and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function detects and summarises available, matched, new and disappearing products on the basis of their prodIDs. It compares products from the base period (start) with products from the current period (end). It returns a list containing the following objects: details with prodIDs of available, matched, new and disappearing products, statistics with basic statistics for them and figure with a pie chart describing a contribution of matched, new and disappearing products in a set of available products.

### Examples

```

list<-products(milk, "2018-12","2019-12")
list$details
list$statistics

```

---

products_fig	<i>Function for graphical comparison of available, matched, new as well as disappearing products.</i>
--------------	---

---

### Description

This function returns a figure with plots of volume (or contributions) of available, matched, new as well as disappearing products.

### Usage

```
products_fig(
  data,
  start,
  end,
  show = c("available", "matched", "new", "disappearing"),
  fixed_base = TRUE,
  contributions = TRUE,
  date_breaks = "1 month"
)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01') and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
show	A character vector indicating which groups of products are to be taken into consideration. Available options are available, matched, new and disappearing.
fixed_base	A logical parameter indicating whether each month is to be compared to the base period (TRUE) or to the previous month (then it is set to FALSE).
contributions	A logical parameter indicating whether contributions or volumes counted for available, matched, new and disappearing products are to be displayed.
date_breaks	A string giving the distance between breaks on the X axis like "1 month" (default value) or "4 months".

### Value

This function returns a figure with plots of volume (or contributions) of available, matched, new as well as disappearing products. The User may control which groups of products are to be taken into consideration (see the show parameter). Available options are available, matched, new and disappearing.

**Examples**

```
products_fig(milk, "2018-12", "2019-04",
fixed_base=TRUE, contributions=FALSE,
show=c("new", "disappearing", "matched", "available"))
```

QMp

*Calculating the quadratic mean of order r price index***Description**

This function returns a value (or vector of values) of the quadratic mean of order r price index.

**Usage**

```
QMp(data, start, end, r = 2, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the quadratic mean of order r price index - see CPI Manual (2004), Section 17.40, formula 17.35 (page 321).

**References**

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
QMp(sugar, start="2019-01", end="2020-01")
QMp(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

QMq

*Calculating the quadratic mean of order r quantity index***Description**

This function returns a value (or vector of values) of the quadratic mean of order r quantity index.

**Usage**

```
QMq(data, start, end, r = 2, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
r	The real and non-zero parameter.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the quadratic mean of order r quantity index - see CPI Manual (2004), Section 17.35, formula 17.30 (page 321).

**References**

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
QMq(sugar, start="2019-01", end="2020-01")
QMq(sugar, start="2019-01", end="2020-01", r=1.3, interval=TRUE)
```

---

QU *Calculating the quality adjusted unit value index (QU index)*

---

**Description**

This function returns a value of the quality adjusted unit value index (QU index) for a given set of adjustment factors.

**Usage**

```
QU(data, start, end, v)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
v	The data frame with adjustment factors for at least all matched prodIDs. It must contain two columns: prodID (as numeric or character) with unique product IDs and values (as positive numeric) with corresponding adjustment factors.

**Value**

This function returns a value of the quality adjusted unit value index (QU index) for a given set of adjustment factors (adjusted factors must be available for all matched prodIDs).

**References**

Chessa, A.G. (2016). *A New Methodology for Processing Scanner Data in the Dutch CPI*. Eurona 1/2016, 49-69.

**Examples**

```
## Creating a data frame with artificial adjustment factors
## (random numbers from uniform distribution U[1,2])
prodID<-unique(milk$prodID)
values<-stats::runif(length(prodID),1,2)
v<-data.frame(prodID,values)
## Calculating the QU index for the created data frame 'v'
QU(milk, start="2018-12", end="2019-12", v)
```

---

quantities	<i>Providing quantities of sold products</i>
------------	--

---

**Description**

The function returns quantities of sold products with given IDs.

**Usage**

```
quantities(data, period, set = c(), ID = FALSE)
```

**Arguments**

data	The user's data frame. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), quantities (as positive numeric) and prodID (as numeric, factor or character) with unique product IDs.
period	The time period (as character) limited to the year and month, e.g. "2019-03".
set	The set of unique product IDs to be used for determining quantities of sold products (see also <a href="#">data_matching</a> ). If the set is empty, the function returns quantities of all products being available in period.
ID	A logical parameter indicating whether a data frame with prodIDs and quantities should be returned.

**Value**

The function analyzes the user's data frame and returns quantities of products with given ID and being sold in the time period indicated by the period parameter. Please note that the function returns the quantity values for sorted prodIDs and in the absence of a given prodID in the data set, the function returns nothing (it does not return zero). If the ID parameter is set to TRUE then the function returns a data frame with columns: by (IDs of products) and q (quantities of products).

**Examples**

```
quantities(milk, period="2019-06")
quantities(milk, period="2019-12", set=c(400032, 82919), ID=TRUE)
```

---

resultant_index	<i>A general function to compute a resultant bilateral price index on the basis of partial price indices</i>
-----------------	--

---

**Description**

This function returns the resultant price index based on partial price indices, the system of weights from the base and current periods, and taking into account the aggregation formula specified by the user.

**Usage**

```
resultant_index(w0 = c(), wt = c(), subindices = c(), aggr = "fisher")
```

**Arguments**

`w0` A vector of positive weights from the base period that sum to one.

`wt` A vector of positive weights from the current period that sum to one.

`subindices` A numeric vector of partial indices.

`aggr` The formula used for aggregating partial index results (available values are: "arithmetic", "geometric", "laspeyres", "paasche", "fisher", "tornqvist").

**Value**

This function returns the resultant bilateral price index based on partial price indices, the system of weights from the base and current periods (if needed), and taking into account the aggregation formula specified by the user. The user can apply the following formulas to aggregate partial indices: the unweighted arithmetic mean, the unweighted geometric mean, the Laspeyres index formula, the Paasche index formula, the Fisher index formula, and the Törnqvist index formula. The aggregation formula is selected using the `aggr` parameter.

**Examples**

```
resultant_index(w0 = c(0.4, 0.4, 0.2),
subindices = c(1.1, 0.95, 1.12), aggr = "laspeyres")
resultant_index(w0 = c(0.4, 0.4, 0.2), wt = c(0.35, 0.5, 0.15),
subindices = c(1.1, 0.95, 1.12), aggr = "fisher")
```

---

retro\_index

---

*Calculating the retrospective price index*

---

**Description**

This function returns values of the selected retrospective price index.

**Usage**

```
retro_index(
  data,
  start,
  end,
  formula = "fisher",
  approach = "correction",
  method_index = "additive",
  method_weights = "additive",
  lambda = "linear",
  sigma = 0.7,
```

```

    df = FALSE,
    name = "RETRO_index"
  )

```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character). A column <code>quantities</code> (as positive numeric) is also needed because this function uses unit values as monthly prices.
<code>start</code>	The base period, being the first expenditure reference period (as character), limited to the year and month, e.g. "2020-03". We assume that the quantity (and thus expenditure) information is available for this period.
<code>end</code>	The second expenditure reference period (as character) limited to the year and month, e.g. "2020-04". We assume that the quantity (and thus expenditure) information is available for this period.
<code>formula</code>	A parameter indicating which index formula to use within the correction or imputation approach, with the values 'fisher' and 'tornqvist' available. If the parameter value is set to 'dhkh', then the retrospective Diewert-Huwiler-Kohli-Hansen index (DHKH) will be computed instead of the correction or imputation method.
<code>approach</code>	A parameter indicating which approach to use to obtain retrospectively computed price indices. Available options are: 'correction', 'imputation', 'correction-imputation', or 'CES-imputation'.
<code>method_index</code>	A parameter indicating how to apply the correction approach. Available options are: 'additive' and 'multiplicative'.
<code>method_weights</code>	A parameter indicating how to apply the imputation approach for calculating weights for all periods within the time interval. Available options are: 'additive' and 'multiplicative'.
<code>lambda</code>	A parameter indicating the relevance of the second expenditure reference period relative to the relevance of the first (base) expenditure reference period. Available options are: 'linear' and 'sinusoidal'.
<code>sigma</code>	A parameter indicating elasticity of substitution.
<code>df</code>	A parameter indicating whether the function should return a data frame with dates and retrospective index values (TRUE) or just a vector of its values for subsequent months (FALSE).
<code>name</code>	A parameter indicating the index (or method) name returned in a resulting data frame.

### Value

The function returns values of the selected retrospective price index for all period between `start` and `end` (`start` is always the fixed base period). Depending on the `formula` parameter it can provide values of the Diewert-Huwiler-Kohli-Hansen index (DHKH) or run correction and imputation approach, as well as the mixture of them, to obtain a vector (or a data frame) of retrospective price

indices. Note that the 'CES-imputation' approach requires elasticity of substitution. The user may control the relevance of the second expenditure reference period (end) relative to the relevance of the first (base) expenditure reference period (start) by using the lambda parameter.

## References

von Auer, L., (2024). *Retrospective computations of price index numbers: theory and application*. *Review of Income and Wealth*, 70(1), 60-79.

## Examples

```
retro_index(milk, start="2018-12",end="2019-04",formula="dhkh", df=TRUE)
retro_index(milk, start="2018-12",end="2019-04", approach="correction",
method_index = "multiplicative", lambda="sinusoidal")
```

---

sales

*Providing values of product sales*

---

## Description

The function returns values of sales of products with given IDs.

## Usage

```
sales(data, period, set = c(), shares = FALSE, hist = FALSE)
```

## Arguments

data	The user's data frame. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character) with unique product IDs.
period	The time period (as character) limited to the year and month, e.g. "2019-03".
set	The set of unique product IDs to be used for determining product sales values (see also <a href="#">data_matching</a> ). If the set is empty, then the function returns sale values of all products being available in period.
shares	A logical parameter indicating whether the function is to return shares of product sales.
hist	A logical parameter indicating whether the function is to return histogram of product sales.

**Value**

The function analyzes the user's data frame and returns values of sales of products with given IDs and being sold in time period indicated by the period parameter (see also expenditures function which returns the expenditure values for sorted prodIDs).

**Examples**

```
sales(milk, period="2019-06", shares=TRUE, hist=TRUE)
sales(milk, period="2019-12", set=unique(milk$prodID)[1])
```

---

sales_groups	<i>Providing information about sales of products from one or more datasets</i>
--------------	--

---

**Description**

The function returns values of sales of products from one or more datasets or the corresponding barplot for these sales.

**Usage**

```
sales_groups(
  datasets = list(),
  start,
  end,
  shares = FALSE,
  barplot = FALSE,
  names = c()
)
```

**Arguments**

datasets	A list of user's data frames. Each data frame must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric) and quantities (as positive numeric).
start	The beginning of the considered time interval (as character) limited to the year and month, e.g. "2020-03".
end	The end of the considered time interval (as character) limited to the year and month, e.g. "2020-04".
shares	A logical parameter indicating whether the function is to calculate shares of product sales
barplot	A logical parameter indicating whether the function is to return barplot for product sales.
names	A vector of characters describing product groups defined by datasets.

**Value**

The function returns values of sales of products from one or more datasets or the corresponding barplot for these sales (if `barplot` is `TRUE`). Alternatively, it calculates the sale shares (if `shares` is `TRUE`).

**Examples**

```
## Creating 3 subgroups of milk:
ctg<-unique(milk$description)
categories<-c(ctg[1],ctg[2],ctg[3])
milk1<-dplyr::filter(milk, milk$description==categories[1])
milk2<-dplyr::filter(milk, milk$description==categories[2])
milk3<-dplyr::filter(milk, milk$description==categories[3])
## Sample use of this function:
sales_groups(datasets=list(milk1,milk2,milk3),start="2019-04",end="2019-04",shares=TRUE)
sales_groups(datasets=list(milk1,milk2,milk3),start="2019-04",end="2019-07",
barplot=TRUE, names=categories)
```

---

sales\_groups2

*Providing information about sales of products*

---

**Description**

The function returns values of sales of products or the corresponding barplot for these sales.

**Usage**

```
sales_groups2(
  data = data.frame(),
  by,
  start,
  end,
  shares = FALSE,
  barplot = FALSE,
  names = c()
)
```

**Arguments**

<code>data</code>	The user's data frame with subgroups of sold products (see <code>by</code> parameter). The data frame must contain columns: <code>time</code> (as <code>Date</code> in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric) and <code>quantities</code> (as positive numeric). An additional column indicated via <code>by</code> parameter is also needed.
<code>by</code>	The column name indicating grouping variable, i.e. this column is used for creating subgroups of products.
<code>start</code>	The beginning of the considered time interval (as character) limited to the year and month, e.g. "2020-03".

end	The end of the considered time interval (as character) limited to the year and month, e.g. "2020-04".
shares	A logical parameter indicating whether the function is to calculate shares of product sales
barplot	A logical parameter indicating whether the function is to return barplot for product sales.
names	A vector of characters describing product groups defined by datasets.

### Value

The function returns values of sales of products or the corresponding barplot for these sales (if barplot is TRUE). Alternatively, it calculates the sale shares (if shares is TRUE).

### Examples

```
outlets<-as.character(unique(milk$retID))
sales_groups2(milk,by="retID",start="2019-04",end="2019-04",
shares=TRUE,barplot=TRUE,names=outlets)
```

---

sato\_vartia

*Calculating the bilateral Vartia-II (Sato-Vartia) price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Vartia-II (Sato-Vartia) price index.

### Usage

```
sato_vartia(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start,end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Vartia-II (Sato-Vartia) price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
sato_vartia(sugar, start="2018-12", end="2019-12")
sato_vartia(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

shrinkflation

*Detecting and summarising downsized and upsized products.*

---

**Description**

This function detects and summarises downsized and upsized products.

**Usage**

```
shrinkflation(
  data,
  start,
  end,
  type = "shrinkflation",
  min_p_change = 0,
  max_p_change = Inf,
  min_s_change = 0,
  max_s_change = Inf,
  prec = 3,
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01') and <code>prodID</code> (as numeric, factor or character), <code>prices</code> (with standardised prices!) and <code>quantities</code> (as numeric), <code>grammage</code> (as numeric), <code>unit</code> (as character) and <code>description</code> (as character). Important: prices must be standardized beforehand, that is, they must refer to the sales unit (the <code>data_norm</code> function can be used for this).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2024-01".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2024-02".
<code>type</code>	A parameter specifying what phenomenon is to be included in the resulting elements of the returned list (i.e. in returned <code>products_detected</code> , <code>df_detected</code> and <code>df_reduced</code> ). The available values are: <code>shrinkflation</code> , <code>shrinkdeflation</code> , <code>sharkflation</code> , <code>unshrinkdeflation</code> , <code>unshrinkflation</code> and <code>sharkdeflation</code> (default value is: <code>shrinkflation</code> ).
<code>min_p_change</code>	Lower limit for unit price change, i.e.: a product is considered if the percentage change in its unit price is greater than the value of this parameter. The default value is zero, possibly positive values can be considered (in percentage).
<code>max_p_change</code>	Upper limit for unit price change, i.e.: a product is considered if the percentage change in its unit price is less than the value of this parameter. The default value is <code>Inf</code> , possibly positive values can be considered (in percentage).
<code>min_s_change</code>	Lower limit for size change, i.e.: a product is considered if the percentage change in its size is greater than the value of this parameter. The default value is zero, possibly positive values can be considered (in percentage).
<code>max_s_change</code>	Upper limit for size change, i.e.: a product is considered if the percentage change in its size is less than the value of this parameter. The default value is <code>Inf</code> , possibly positive values can be considered (in percentage).
<code>prec</code>	Number of decimal places for the presented summary results.
<code>interval</code>	A parameter that specifies whether the search for downsized products should consider the entire time interval, or only the compared months specified by the <code>start</code> and <code>end</code> parameters.

**Value**

This function detects and summarises downsized and upsized products. The function detects phenomena such as: `shrinkflation`, `shrinkdeflation`, `sharkflation`, `unshrinkdeflation`, `unshrinkflation`, `sharkdeflation` (see the `type` parameter). It returns a list containing the following objects: `df_changes` - data frame with detailed information on downsized and upsized products with the whole history of size changes, `df_type` - data frame with recognized type of products, `df_overview` - a table with basic summary of all detected products grouped by the `type` parameter, `products_detected` with `prodIDs` of products indicated by the 'type' parameter, `df_detected` being a subset of the data frame with only detected products, `df_reduced` which is the difference of the input data frame and the data frame containing the detected products, and `df_summary` which provides basic statistics for all detected downsized and upsized products (including their share in the total number of products and mean price and size changes).

---

 SPQ

---

*Calculating the multilateral SPQ price index*

---

## Description

This function returns a value of the multilateral SPQ price index which is based on the relative price and quantity dissimilarity measure.

## Usage

```
SPQ(data, start, end, interval = FALSE)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. '2019-03'.

end	The research period (as character) limited to the year and month, e.g. '2019-07'.
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

This function returns a value of the multilateral SPQ price index which is based on the relative price and quantity dissimilarity measure (see References). If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
SPQ(sugar, start="2018-12",end="2019-02")
SPQ(milk, start="2018-12",end="2019-12",interval=TRUE)
```

---

stuvcl

*Calculating the bilateral Stuvcl price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Stuvcl price index.

### Usage

```
stuvcl(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

`interval` A logical value indicating whether the function is to compare the research period defined by `end` to the base period defined by `start` (then `interval` is set to `FALSE`) or all fixed base indices are to be calculated. In this latter case, all months from the time interval `<start,end>` are considered and `start` defines the base period (`interval` is set to `TRUE`).

### Value

The function returns a value (or vector of values) of the bilateral Stuvcl price index depending on the `interval` parameter. If the `interval` parameter is set to `TRUE`, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
stuvcl(sugar, start="2018-12", end="2019-12")
stuvcl(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

sugar

*A real data set on sold sugar*

---

### Description

A collection of scanner data on the sale of sugar in one of Polish supermarkets in the period from December 2017 to October 2020

### Usage

```
sugar
```

### Format

A data frame with 6 columns and 7666 rows. The used variables are as follows:

`time` - Dates of transactions (Year-Month-Day)

`prices` - Prices of sold products [PLN]

`quantities` - Quantities of sold products [kg]

`prodID` - Unique product codes (data set contains 11 different prodIDs)

retID - Unique codes identifying outlets/retailer sale points (data set contains 20 different retIDs)  
 description Descriptions of sold sugar products (data set contains 3 different product descriptions)

---

theil1 *Calculating the bilateral Theil I price index*

---

### Description

This function returns a value (or vector of values) of the bilateral geometric Theil I price index.

### Usage

```
theil1(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral geometric Theil I price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

tindex	<i>Calculating theoretical (expected) values of the unweighted price index</i>
--------	--

---

### Description

This function calculates the theoretical value of the unweighted price index for lognormally distributed prices.

### Usage

```
tindex(pmi = c(), psigma = c(), start, ratio = TRUE)
```

### Arguments

pmi	A numeric vector indicating $\mu$ parameters for lognormally distributed prices from the subsequent months.
psigma	A numeric vector indicating $\sigma$ parameters for lognormally distributed prices from the subsequent months.
start	The first period in the generated data frame (as character) limited to the year and month, e.g. '2019-12'.
ratio	A logical parameter indicating how we define the theoretical unweighted price index. If it is set to TRUE, then the resulting value is a ratio of expected price values from compared months; otherwise the resulting value is the expected value of the ratio of prices from compared months.

### Value

This function calculates the theoretical value of the unweighted price index for lognormally distributed prices (the month defined by `start` parameter plays a role of the fixed base period). The characteristics for these lognormal distributions are set by `pmi` and `sigma` parameters. The `ratio` parameter allows to control the definition of resulting theoretical price index values. The function provides a data frame consisting of dates and corresponding expected values of the theoretical unweighted price index. The generated dataset is ready for further price index calculations.

### Examples

```
tindex(pmi=c(1,1.2,1.3),psigma=c(0.1,0.2,0.15),start="2020-01")  
tindex(pmi=c(1,1.2,1.3),psigma=c(0.1,0.2,0.15),start="2020-01",ratio=FALSE)
```

tornqvist

*Calculating the bilateral Tornqvist price index***Description**

This function returns a value (or vector of values) of the bilateral Tornqvist price index.

**Usage**

```
tornqvist(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the bilateral Tornqvist price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

**Examples**

```
tornqvist(sugar, start="2018-12", end="2019-12")
tornqvist(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

tpd *Calculating the multilateral TPD price index*

---

### Description

This function returns a value of the multilateral TPD (Time Product Dummy) price index.

### Usage

```
tpd(data, start, end, wstart = start, window = 13)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral TPD price index which considers the time window defined by wstart and window parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). Please note that a Weighted Least Squares (WLS) regression is run with the expenditure shares in each period serving as weights. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### References

### Examples

```
tpd(milk, start="2019-01", end="2019-08", window=10)
tpd(milk, start="2018-12", end="2019-12")
```

---

tpd_fbew	<i>Extending the multilateral TPD price index by using the FBEW method.</i>
----------	---

---

### Description

This function returns a value of the multilateral TPD price index (Time Product Dummy index) extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

### Usage

```
tpd_fbew(data, start, end)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function returns a value of the multilateral TPD price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```
tpd_fbew(milk, start="2018-12", end="2019-08")
```

---

tpd_fbmw	<i>Extending the multilateral TPD price index by using the FBMW method.</i>
----------	---

---

### Description

This function returns a value of the multilateral TPD price index (Time Product Dummy index) extended by using the FBMW (Fixed Base Moving Window) method.

### Usage

```
tpd_fbmw(data, start, end)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function returns a value of the multilateral TPD price index extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

Lamboray, C.(2017). *The Geary Khamis index and the Lehr index: how much do they differ?* Paper presented at the 15th Ottawa Group meeting, 10-12 May 2017, Elville am Rhein, Germany.

### Examples

```
tpd_fbmw(milk, start="2019-12", end="2020-04")
```

---

tpd_splice	<i>Extending the multilateral TPD price index by using window splicing methods.</i>
------------	---

---

### Description

This function returns a value (or values) of the multilateral TPD price index (Time Product Dummy index) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

### Usage

```
tpd_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

### Value

This function returns a value or values (depending on interval parameter) of the multilateral TPD price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published

indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: `price_indices` or `final_index`. The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the `final_index` function).

unit_value_index	<i>Calculating the unit value index</i>
------------------	---

---

## Description

This function returns a value (or vector of values) of the unit value index

## Usage

```
unit_value_index(data, start, end, interval = FALSE)
```

## Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day,e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
-------------------	---

start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the unit value index. The value index is calculated as the unit value at time start divided by the unit value at time start.

### References

(2004). *Consumer Price Index Manual. Theory and practice*. ILO/IMF/OECD/UNECE/Eurostat/The World Bank, International Labour Office (ILO), Geneva.

### Examples

```
unit_value_index(sugar, start="2019-01", end="2020-01")
unit_value_index(sugar, start="2019-01", end="2020-01", interval=TRUE)
```

---

utpd

---

*Calculating the unweighted multilateral TPD price index*

---

### Description

This function returns a value of the unweighted multilateral TPD (Time Product Dummy) price index.

### Usage

```
utpd(data, start, end, wstart = start, window = 13)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the unweighted multilateral TPD price index which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). Please note, that the estimation procedure runs the Ordinary Least Squares (OLS) method instead of the Weighted Least Squares (WLS) method like in the case of the TPD index. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

**References**

de Haan, J. and F. Krsinich (2014). *Time Dummy Hedonic and Quality-Adjusted Unit Value Indexes: Do They Really Differ?* Paper presented at the Society for Economic Measurement Conference, 18-20 August 2014, Chicago, U.S.

**Examples**

```
utpd(milk, start="2019-01", end="2019-08", window=10)
utpd(milk, start="2018-12", end="2019-12")
```

---

utpd_fbew	<i>Extending the unweighted multilateral TPD price index by using the FBEW method.</i>
-----------	--

---

**Description**

This function returns a value of the unweighted multilateral TPD price index (Time Product Dummy index) extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
utpd_fbew(data, start, end)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the unweighted multilateral TPD price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

utpd\_splice

*Extending the multilateral unweighted TPD price index by using window splicing methods.*

---

**Description**

This function returns a value (or values) of the unweighted multilateral TPD price index (Time Product Dummy index) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
utpd_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the unweighted multilateral TPD price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
utpd_splince(milk, start="2018-12", end="2020-02", splince="half")
```

---

value\_index

*Calculating the value index*

---

**Description**

This function returns a value (or vector of values) of the value index

**Usage**

```
value_index(data, start, end, interval = FALSE)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the value index. The value index is calculated as sum of expenditures from period end divided by sum of expenditures from period start.

**References**

**Examples**

```
value_index(sugar, start="2019-01", end="2020-01")
value_index(sugar, start="2019-01", end="2020-01", interval=TRUE)
```

---

vartia *Calculating the bilateral Vartia-I price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Vartia-I price index.

### Usage

```
vartia(data, start, end, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Vartia-I price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

wgeks

*Calculating the multilateral weighted WGEKS price index***Description**

This function returns a value of the multilateral weighted WGEKS price index (to be more precise: the weighted GEKS index based on the Fisher formula).

**Usage**

```
wgeks(data, start, end, wstart = start, window = 13)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral weighted WGEKS price index (to be more precise: the weighted GEKS index based on the Fisher formula) which considers the time window defined by wstart and window parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

wgeks(milk, start="2018-12", end="2019-12")
```

wgeksaqi

*Calculating the multilateral weighted WGEKS-AQI price index***Description**

This function returns a value of the multilateral weighted WGEKS-AQI price index (to be more precise: the weighted GEKS index based on the asynchronous quality adjusted price index formula).

**Usage**

```
wgeksaqi(data, start, end, wstart = start, window = 13)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral weighted WGEKS-AQI price index (to be more precise: the weighted GEKS index based on the asynchronous quality adjusted price index formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

Białek, J. (2023). *Quality adjusted GEKS-type indices for price comparisons based on scanner data*. *Statistics in Transition – new series*, 24(3), 151-169.

## Examples

```
wgeksaqi(milk, start="2019-01", end="2019-08",window=10)
wgeksaqi(milk, start="2018-12", end="2019-12")
```

---

wgeksaqi_fbew	<i>Extending the multilateral weighted GEKS-AQI price index by using the FBEW method.</i>
---------------	---

---

## Description

This function returns a value of the multilateral weighted GEKS-AQI price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

## Usage

```
wgeksaqi_fbew(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral weighted GEKS-AQI price index (the weighted GEKS index based on the asynchronous quality adjusted price index formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```
wgeksaqi_fbmw(milk, start="2018-12", end="2019-08")
```

---

wgeksaqi_fbmw	<i>Extending the multilateral weighted GEKS-AQI price index by using the FBMW method.</i>
---------------	---

---

## Description

This function returns a value of the multilateral weighted GEKS-AQI price index extended by using the FBMW (Fixed Base Moving Window) method.

## Usage

```
wgeksaqi_fbmw(data, start, end)
```

## Arguments

- |       |  |
|-------|--|
| data  | The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). |
| start | The base period (as character) limited to the year and month, e.g. "2019-12".  |
| end   | The research period (as character) limited to the year and month, e.g. "2020-04".  |

**Value**

This function returns a value of the multilateral weighted GEKS-AQI price index (the GEKS index based on the asynchronous quality adjusted price index formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

```
wgeksaqi_fbmw(milk, start="2019-12", end="2020-04")
```

---

wgeksaqi_splice	<i>Extending the multilateral weighted GEKS-AQI price index by using window splicing methods.</i>
-----------------	---

---

**Description**

This function returns a value (or values) of the multilateral weighted GEKS-AQI price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
wgeksaqi_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>splice</code>	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
<code>interval</code>	A logical value indicating whether the function is to provide the price index comparing the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by <code>start</code> ).

**Value**

This function returns a value or values (depending on `interval` parameter) of the multilateral weighted GEKS-AQI price index (the weighted GEKS index based on the asynchronous quality adjusted price index formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

wgeksaqu

*Calculating the multilateral weighted WGEKS-AQU price index*

---

## Description

This function returns a value of the multilateral weighted WGEKS-AQU price index (to be more precise: the weighted GEKS index based on the asynchronous quality adjusted unit value formula).

## Usage

```
wgeksaqu(data, start, end, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

**Value**

This function returns a value of the multilateral weighted WGEKS-AQU price index (to be more precise: the weighted GEKS index based on the asynchronous quality adjusted unit value formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

- Białek, J. (2023). *Quality adjusted GEKS-type indices for price comparisons based on scanner data*. *Statistics in Transition – new series*, 24(3), 151-169.

**Examples**

```
wgeksaqu(milk, start="2019-01", end="2019-08", window=10)
wgeksaqu(milk, start="2018-12", end="2019-12")
```

---

wgeksaqu\_fbew

*Extending the multilateral weighted GEKS-AQU price index by using the FBEW method.*

---

**Description**

This function returns a value of the multilateral weighted GEKS-AQU price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

**Usage**

```
wgeksaqu_fbew(data, start, end)
```

**Arguments**

`data` The user's data frame with information about sold products. It must contain columns: `time` (as Date in format: year-month-day, e.g. '2020-12-01'), `prices` (as positive numeric), `quantities` (as positive numeric) and `prodID` (as numeric, factor or character).

start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function returns a value of the multilateral weighted GEKS-AQU price index (the weighted GEKS index based on the asynchronous quality adjusted unit value formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

```

---

wgeksaqu_fbmw	<i>Extending the multilateral weighted GEKS-AQU price index by using the FBMW method.</i>
---------------	---

---

### Description

This function returns a value of the multilateral weighted GEKS-AQU price index extended by using the FBMW (Fixed Base Moving Window) method.

### Usage

```
wgeksaqu_fbmw(data, start, end)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

**Value**

This function returns a value of the multilateral weighted GEKS-AQU price index (the GEKS index based on the asynchronous quality adjusted unit value formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product sub-groups (to consider these types of aggregating, please use the [final\\_index](#) function).

**Examples**

```
wgeksaqu_fbmw(milk, start="2019-12", end="2020-04")
```

---

wgeksaqu\_splice

---

*Extending the multilateral weighted GEKS-AQU price index by using window splicing methods.*

---

**Description**

This function returns a value (or values) of the multilateral weighted GEKS-AQU price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
wgeksaqu_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2019-12".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
<code>splice</code>	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
<code>interval</code>	A logical value indicating whether the function is to provide the price index comparing the research period defined by <code>end</code> to the base period defined by <code>start</code> (then <code>interval</code> is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by <code>start</code> ).

**Value**

This function returns a value or values (depending on `interval` parameter) of the multilateral weighted GEKS-AQU price index (the weighted GEKS index based on the asynchronous quality adjusted unit value formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in `start` and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
wgeksgaqi_splce(milk, start="2018-12", end="2020-02", splce="half")
```

---

wgeksgaqi

*Calculating the multilateral weighted WGEKS-GAQI price index*

---

## Description

This function returns a value of the multilateral weighted WGEKS-GAQI price index (to be more precise: the weighted GEKS index based on the geometric asynchronous quality adjusted price index formula).

## Usage

```
wgeksgaqi(data, start, end, wstart = start, window = 13)
```

## Arguments

- |       |  |
|-------|--|
| data  | The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character). |
| start | The base period (as character) limited to the year and month, e.g. "2020-03".  |
| end   | The research period (as character) limited to the year and month, e.g. "2020-04".  |

wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral weighted WGEKS-GAQI price index (to be more precise: the weighted GEKS index based on the geometric asynchronous quality adjusted price index formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

wgeksgaqi_splice	<i>Extending the multilateral weighted GEKS-GAQI price index by using window splicing methods.</i>
------------------	--

---

**Description**

This function returns a value (or values) of the multilateral weighted GEKS-GAQI price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

**Usage**

```
wgeksgaqi_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

**Arguments**

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

**Value**

This function returns a value or values (depending on interval parameter) of the multilateral weighted GEKS-GAQI price index (the weighted GEKS index based on the geometric asynchronous quality adjusted price index formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). ```

---

wgeksgl

*Calculating the multilateral weighted WGEKS-GL price index*

---

**Description**

This function returns a value of the multilateral weighted WGEKS-GL price index (to be more precise: the weighted GEKS index based on the geometric Laspeyres formula).

**Usage**

```
wgeksgl(data, start, end, wstart = start, window = 13)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
wstart	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

## Value

This function returns a value of the multilateral weighted WGEKS-GL price index (to be more precise: the weighted GEKS index based on the geometric Laspeyres formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both start and end must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

---

wgeksgl_fbew	<i>Extending the multilateral weighted GEKS-GL price index by using the FBEW method.</i>
--------------	--

---

### Description

This function returns a value of the multilateral weighted GEKS-GL price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

### Usage

```
wgeksgl_fbew(data, start, end)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

### Value

This function returns a value of the multilateral weighted GEKS-GL price index (the weighted GEKS index based on the geometric Laspeyres formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods `end` and `start`. The month of the `start` parameter must be December. If the distance between `end` and `start` exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
wgeksgl_fbmw(milk, start="2018-12", end="2019-08")
```

---

wgeksgl_fbmw	<i>Extending the multilateral weighted GEKS-GL price index by using the FBMW method.</i>
--------------	--

---

## Description

This function returns a value of the multilateral weighted GEKS-GL price index extended by using the FBMW (Fixed Base Moving Window) method.

## Usage

```
wgeksgl_fbmw(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral weighted GEKS-GL price index (the GEKS index based on the geometric Laspeyres formula) extended by using the FBMW (Fixed Base Moving Window) method. It measures the price dynamics between periods end and start and it uses a 13-month time window with a fixed base month taken as year(end)-1. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. The month of the start parameter must be December. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
wgeksgl_fbmw(milk, start="2019-12", end="2020-04")
```

---

wgeksgl_splice	<i>Extending the multilateral weighted GEKS-GL price index by using window splicing methods.</i>
----------------	--

---

## Description

This function returns a value (or values) of the multilateral weighted GEKS-GL price index extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References).

## Usage

```
wgeksgl_splice(
  data,
  start,
  end,
  window = 13,
  splice = "movement",
  interval = FALSE
)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
------	---

start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
window	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).
splice	A character string indicating the splicing method. Available options are: "movement", "window", "half", "mean", "window_published", "half_published", "mean_published".
interval	A logical value indicating whether the function is to provide the price index comparing the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base multilateral indices are to be presented (the fixed base month is defined by start).

### Value

This function returns a value or values (depending on interval parameter) of the multilateral weighted GEKS-GL price index (the weighted GEKS index based on the geometric Laspeyres formula) extended by using window splicing methods. Available splicing methods are: movement splice, window splice, half splice, mean splice and their additional variants: window splice on published indices (WISP), half splice on published indices (HASP) and mean splice on published indices (see References). The time window starts in start and should consist of at least two months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

### Examples

```
wgeksgl_splice(milk, start="2018-12", end="2020-02", splice="half")
```

---

`wgeksl`*Calculating the multilateral weighted WGEKS-L price index*

---

### Description

This function returns a value of the multilateral weighted WGEKS-L price index (to be more precise: the weighted GEKS index based on the Laspeyres formula).

### Usage

```
wgeksl(data, start, end, wstart = start, window = 13)
```

### Arguments

<code>data</code>	The user's data frame with information about sold products. It must contain columns: <code>time</code> (as Date in format: year-month-day, e.g. '2020-12-01'), <code>prices</code> (as positive numeric), <code>quantities</code> (as positive numeric) and <code>prodID</code> (as numeric, factor or character).
<code>start</code>	The base period (as character) limited to the year and month, e.g. "2020-03".
<code>end</code>	The research period (as character) limited to the year and month, e.g. "2020-04".
<code>wstart</code>	The beginning of the time interval (which is used by multilateral methods) limited to the year and month, e.g. "2020-01".
<code>window</code>	The length of the time window (as positive integer: typically multilateral methods are based on the 13-month time window).

### Value

This function returns a value of the multilateral weighted WGEKS-L price index (to be more precise: the weighted GEKS index based on the Laspeyres formula) which considers the time window defined by `wstart` and `window` parameters. It measures the price dynamics by comparing period end to period start (both `start` and `end` must be inside the considered time window). To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

## Examples

```
wgekssl(milk, start="2019-01", end="2019-08", window=10)
wgekssl(milk, start="2018-12", end="2019-12")
```

---

wgekssl_fbew	<i>Extending the multilateral weighted GEKS-L price index by using the FBEW method.</i>
--------------	---

---

## Description

This function returns a value of the multilateral weighted GEKS-L price index extended by using the FBEW (Fixed Base Monthly Expanding Window) method.

## Usage

```
wgekssl_fbew(data, start, end)
```

## Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2019-12".
end	The research period (as character) limited to the year and month, e.g. "2020-04".

## Value

This function returns a value of the multilateral weighted GEKS-L price index (the weighted GEKS index based on the Laspeyres formula) extended by using the FBEW (Fixed Base Monthly Expanding Window) method. The FBEW method uses a time window with a fixed base month every year (December). The window is enlarged every month with one month in order to include information from a new month. The full window length (13 months) is reached in December of each year. The function measures the price dynamics between periods end and start. The month of the start parameter must be December. If the distance between end and start exceeds 13 months, then internal Decembers play a role of chain-linking months. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).

wgeks_splice(milk, start="2018-12", end="2020-02",splice="half")
```

ybmd

*Calculating the unweighted YBMD price index***Description**

This function returns a value (or vector of values) of the unweighted Young-Balk-Mehrhoff-Dikhanov (YBMD) price index.

**Usage**

```
ybmd(data, start, end, interval = FALSE)
```

**Arguments**

data	User's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day,e.g. '2020-12-01'), prices (as positive numeric) and prodID (as numeric, factor or character). A column quantities (as positive numeric) is also needed because this function uses unit values as monthly prices.
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

**Value**

The function returns a value (or vector of values) of the unweighted bilateral YBMD price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function). This function returns values identical to those of the BMW and YBMD indices (three different names for this index are used in the literature).

### Examples

```
ybmd(sugar, start="2018-12", end="2019-12")
ybmd(milk, start="2018-12", end="2020-01", interval=TRUE)
```

---

young

*Calculating the bilateral Young price index*

---

### Description

This function returns a value (or vector of values) of the bilateral Young price index.

### Usage

```
young(data, start, end, base = start, interval = FALSE)
```

### Arguments

data	The user's data frame with information about sold products. It must contain columns: time (as Date in format: year-month-day, e.g. '2020-12-01'), prices (as positive numeric), quantities (as positive numeric) and prodID (as numeric, factor or character).
start	The base period (as character) limited to the year and month, e.g. "2020-03".
end	The research period (as character) limited to the year and month, e.g. "2020-04".
base	The prior period used in the Young price index formula (as character) limited to the year and month, e.g. "2020-01"
interval	A logical value indicating whether the function is to compare the research period defined by end to the base period defined by start (then interval is set to FALSE) or all fixed base indices are to be calculated. In this latter case, all months from the time interval <start, end> are considered and start defines the base period (interval is set to TRUE).

### Value

The function returns a value (or vector of values) of the bilateral Young price index depending on the interval parameter. If the interval parameter is set to TRUE, the function returns a vector of price index values without dates. To get information about both price index values and corresponding dates, please see functions: [price\\_indices](#) or [final\\_index](#). The function does not take into account aggregating over outlets or product subgroups (to consider these types of aggregating, please use the [final\\_index](#) function).
